# Using Stored Procedures, Views, and Triggers

## How to Use Stored Procedures, Views, and Triggers

SERVER-SIDE PROCESSING, which is when you let a server process your queries and the like, is probably a concept you have heard of and it's the very topic of this chapter. Well, to some extent anyway. I discuss three specific ways of doing server-side processing: stored procedures, triggers, and views. The good thing about server-side processing is that you can use the power and resources of your server for doing purely data-related processing and thus leave your client free to do other stuff, and your network clearer of data that the client doesn't want. It's not always appropriate to do so, but in many cases you can benefit from it.

This chapter includes several hands-on exercises that will take you through creating stored procedures, views, and triggers. See the Exercise items that appear throughout the text.

Although this chapter primarily focuses on SQL Server 2000 features, some of the functionality can certainly be reproduced in the other DBMSs I cover in this book:

- *SQL Server 7.0:* All functionality shown in this chapter can be reproduced. However, SQL Server 7.0 doesn't support the INSTEAD OF triggers described in "Using Triggers."
- *Microsoft Access:* Microsoft Access doesn't support stored procedures or triggers. However, views can be reproduced as queries in Microsoft Access, but you can't do this from within the VS .NET IDE; you have to use other means, like the Microsoft Access front-end. If you are unfamiliar with

Microsoft Access, I can recommend you read the following book to get you up to speed: *From Access to SQL Server*, by Russell Sinclair. Published by Apress, September 2000. ISBN: 1893115-240.

- *Oracle*: Oracle supports all the server-side processing described in this chapter.
- *MySQL*: For the examples in this book, I have been using MySQL version 3.23.45, which doesn't support triggers, views, or stored procedures, meaning there is no example code for MySQL in this chapter. However, at the time of writing (March 2002), an alpha version (4.0) of MySQL is available for download from <http://www.mysql.com>. The final version 4.0 is supposed to support stored procedures, views, and triggers. Even when these server-side processing means are available in MySQL, it's still not possible to create any of these items from within the VS .NET IDE.

The code for this chapter has examples for all the listed DBMSs where appropriate.

## Optimization Issues

When I talk about optimizing performance of an application, there are a number of things to consider, but let's just make one thing clear before I go on: I am only talking distributed applications and not stand-alone applications that sit nicely on a possibly disconnected single PC. These stand-alone applications are also called *single tier* or *monolithic applications*.<sup>1</sup> The applications I discuss here use a network of some sort to access data and business services.

Okay, now that the basics are out of the way, I can focus on the obstacles that can lead to decreasing performance and how you need to know these obstacles well when you start the optimization process. You should keep such obstacles in mind when you design your application. However, the various resources, such as network bandwidth, processor power, available RAM, and so on, most often change over time, and then you'll have to reconsider if your application needs changing.

Table 6-1 lists all the varying factors that can influence the performance of your application, which could be a topic for an entire book. However, although I only describe these factors briefly, I want you to be aware of the resources mentioned; they have great influence on what server-side processing resources you should choose when you design your application. In general, it's often the client queries and not the server itself that create the biggest performance problems.

---

1. Stand-alone applications don't have to be single tier, but they generally are.

Table 6-1. Performance Resources Optimization

RESOURCE NAME	DESCRIPTION
Network resources	When speaking of network resources, I am referring to the actual bandwidth of the network. Consider your network setup—whether you are on a LAN or you are accessing resources over a WAN such as the Internet, and so on. If you have a low bandwidth, it's obvious that you want to transfer as little data across the network as possible. If on the other hand you have plenty of bandwidth, you might want to transfer large amounts of data across the network. However, best practices prescribe that you only transfer the data needed across your network, even when you have wide bandwidth.
Local processing resources	If you have the raw power available on your local box, it can be good to do most of the data processing there. Mind you, it all depends on the available bandwidth and the processing resources on the server.
Server processing resources	Server-side processing is desirable, if the server has resources to do so. Another thing you should consider is whether it has the resources to serve all your clients, if you let the server do some of the data processing.
Data distribution	Although strictly speaking this isn't a resource as such, it's definitely another issue you might need to consider. If your data comes from various different and even disparate data sources, it often doesn't make too much sense to have one server process data from all the data sources, just to send the result set to the client. In most cases, it makes sense to have all the data delivered directly to the client.

Table 6-1 just provides a quick overview. Table 6-2 shows you some different application scenarios.

Table 6-2. Different Application Scenarios

<b>CLIENT MACHINE</b>	<b>SERVER</b>	<b>NETWORK</b>	<b>RECOMMENDATION</b>
Limited processing resources	Plenty of processing resources	Limited bandwidth	Now, this one is obvious. You should use the raw processing power of the server to process the data and only return the requested data. This will save resources on the network and on the client.
Plenty of processing resources	Plenty of processing resources	Limited bandwidth	Hmm, processing could be done on either the client or the server, but it really depends on the amount of data you need to move across the network. If it's a limited amount of data, processing on either side will do, but if it's a lot of data, then let the server do the processing. Another solution could be to store the data locally and then use replication or batch processing to update the server.
Plenty of processing resources	Limited processing resources	Limited bandwidth	In this case, processing should be done on the client, but it really depends on the amount of data you need to move across the network. If it's a limited amount of data, the client should do the processing; but if it's a lot of data, you might consider letting the server do some of the processing, or even better; upgrade your server.
Plenty of processing resources	Limited processing resources	Plenty of bandwidth	Okay, don't think too hard about this one—processing should be done on the client.

I could add plenty more scenarios to the list, but I think you get the picture. You'll rarely encounter a situation that matches a straightforward scenario with a simple answer. It's your job to know about all the potential issues when you design your application and have to decide on where to process your data. Quite often different aspects of an application have different data processing needs, so the answer may vary even within a single application. One book that will help

you with many common problems you may encounter with SQL Server is this one:

- *SQL Server: Common Problems, Tested Solutions*, by Neil Pike. Published by Apress, October 2000. ISBN: 189311581X.

## *Troubleshooting Performance Degradation*

When you realize that you have performance problems or when you just want to optimize your server, you need one or more tools to help. SQL Server and Windows NT/2000 provides a number of tools you can use when troubleshooting and here are a few of them:

- Database Consistency Checker (DBCC) (SQL Server)
- Performance Monitor (Windows NT/2000)
- Query Analyzer (SQL Server)
- System Stored Procedures (SQL Server)

I'll briefly describe what you can use these tools for and give you links for obtaining more information.

### *Database Consistency Checker*

The *Database Consistency Checker* (DBCC) is used for checking the logic as well as the consistency of your databases using T-SQL DBCC statements. Furthermore, many of the DBCC statements can also fix the problems detected when running. DBCC statements are T-SQL enhancements and as such must be run as SQL scripts. Here is one example of a DBCC statement:

```
DBCC CHECKDB
```

This DBCC statement is used for checking the structural integrity of the objects in the database you specify. It can also fix the problems found when running. There are many DBCC statements, and this isn't the place to go over these, but check SQL Server Books Online (included with SQL Server) for more information about DBCC.

## *Performance Monitor*

The *Performance Monitor* (perfmon) is used for tracking and recording activity on your machine or rather any machine within your enterprise. perfmon comes with Windows NT/2000/XP and is located in the Administrative Tools menu, but you can also run it from a command prompt, or the Run facility of Windows Start Menu, by executing perfmon. Any of the Windows platforms mentioned produces counters that can be tracked or polled by perfmon at regular intervals if needed. SQL Server also comes with counters that can be tracked or polled by perfmon. Some of the more general counters are used for polling processor time, disk access, memory usage, and so on. Arguably the best of it all is the ability to save a session of all activity recorded or polled within any given time frame. You can then play back a saved session, whenever appropriate. This is especially important when you want to establish a baseline against which to compare future session recordings.

Check your Windows NT/2000/XP documentation for more information about perfmon.

## *Query Analyzer*

The *Query Analyzer* is an external tool that comes with SQL Server for analyzing and optimizing your queries. You can find it in the menus created by SQL Server Setup.

Query Analyzer can be used for validating your queries in the form of script files and queries you type yourself in the query window. Besides validating a query, you can get Query Analyzer to analyze it by running. The analysis includes an execution plan, statistics, and a trace of the query being executed. Queries can get complicated, and many do when joining tables, and it isn't always obvious how much processing a particular query will take. There's normally more than one way to get to complex data, so the trace is invaluable in optimizing your data requests.

See SQL Server Books Online (included with SQL Server) for more information about Query Analyzer. You can actually invoke the Query Analyzer part of the SQL Server Books Online help text from within Query Analyzer by pressing F1.

## *System Stored Procedures*

The *System Stored Procedures* is a set of stored procedures that comes with SQL Server for database administrators to use for maintaining and administering SQL Server. There are a number of System Stored Procedures, including two XML ones, and I certainly can't cover them here, but I can mention some of the

functionality they cover: they let you see who's logged on to the system, administer registration with Active Directory, set up replication, set up full-text search, create and edit maintenance plans, and administer a database in general.

See SQL Server Books Online (comes with SQL Server) for more information about the System Stored Procedures.

## Using Stored Procedures

A *stored procedure* is a precompiled batch<sup>2</sup> of SQL statement(s) that is stored on the database server. The SQL statements are always executed on the database server. Stored procedures have long been a good way of letting the server process your data. They can significantly reduce the workload on the client, and once you get to know them you'll wonder how you ever managed without them.

There is certainly more to a stored procedure than just mentioned, but I do think this is the most significant aspect of a stored procedure. Think about it: it's a way of grouping a batch of SQL statements, storing it on the database server, and executing it with a single call. The fact that the stored procedure is precompiled will save you time as well when executed. Furthermore, the stored procedure can be executed by any number of users, meaning you might save a lot of bandwidth just by calling the stored procedure instead of sending the whole SQL statement every time.

A stored procedure can contain any SQL statement that your database server can understand. This means you can use stored procedures for various tasks, such as executing queries—both so-called action queries, such as DELETE queries, and row-returning queries, such as SELECT statements.

Another task you can use a stored procedure for is database maintenance. Use it to run cleanup SQL statements when the server is least busy and thus save the time and effort of having to do this manually. I won't cover maintenance tasks in this chapter, but they are important, and you should be aware of the various tasks you can perform with stored procedures. If you're like me, you have been or are working for a small company that doesn't have a database administrator, in which case you're in charge of keeping the database server running. Granted, it's not an ideal situation, but you certainly get to know your DBMS in different ways than you would just being a programmer, and that's not bad at all.

To sum it up: a stored procedure is a precompiled SQL statement or batch of SQL statements that is stored on the database server. All processing takes place on the server, and any result requested by a client is then returned in a prepared format.

---

2. Actually some stored procedures only hold one SQL statement.

## *Why Use a Stored Procedure?*

You should use a stored procedure in the following cases (please note that other cases do apply, depending on your circumstances):

- Executing one or more related SQL statements on a regular basis
- Hiding complex table structures from client developers
- Returning the result of your SQL statements because you have a limited bandwidth on your network
- Delegating data processing to the server because you have limited processing resources on your client
- Ensuring processes are run, on a scheduled basis, without user intervention

Granted, there can be substantially more work in setting up a stored procedure than in just executing the SQL statement(s) straight from the client, but my experience has confirmed that the extra work saves you at least tenfold the time once you start coding and using your application. Even SQL Server itself and other major DBMSs use stored procedures for maintenance and other administrative tasks.

One last thing I want to mention is the fact that if you base a lot of your data calls on stored procedures, it can be much easier to change the data calls at a later date. You can simply change the stored procedure and not the application itself, meaning you don't have to recompile a business service or even your client application, depending on how you have designed your application. On the negative side, stored procedures are often written using database vendor-specific SQL extensions, which mean that they're hard to migrate to a different RDBMS. This of course is only a real concern if you're planning to move to another RDBMS.

---

## Planning a Move to a Different RDBMS

If you're planning to move to another RDBMS from SQL Server, or just want to make it as easy as possible should management decide so in the future, it'll probably be a good idea to look up the following T-SQL statements in the SQL Server Books Online Help Documentation:

- **SET ANSI\_DEFAULTS:** This statement sets the ANSI defaults on for the duration of the query session, trigger, or stored procedure.
- **SET FIPS\_FLAGGER:** This statement can be used to check for compliance with the ANSI SQL-92 standard.

If you use these statements appropriately, they can certainly help ease the move from SQL Server to another ANSI SQL-92-compliant RDBMS.

---

## *Creating and Running a Stored Procedure*

Creating a stored procedure is fairly easy, and you're probably used to working with the Enterprise Manager that comes with SQL Server or a different stored procedure editor for SQL Server or Oracle. If this is the case, you may want to check out the facilities in the Server Explorer in the VS .NET IDE. Among other things, it's much easier to run and test a stored procedure directly from the text editor. Anyway, here's how you would create a stored procedure for the example UserMan database:

1. Open up the Server Explorer window.
2. Expand the UserMan database on your database server.
3. Right-click the Stored Procedures node and select New Stored Procedure.

This brings up the Stored Procedure text editor, which incidentally looks a lot like your C# code editor. Except for syntax checking and other minor stuff, they are exactly the same (see Figure 6-1).

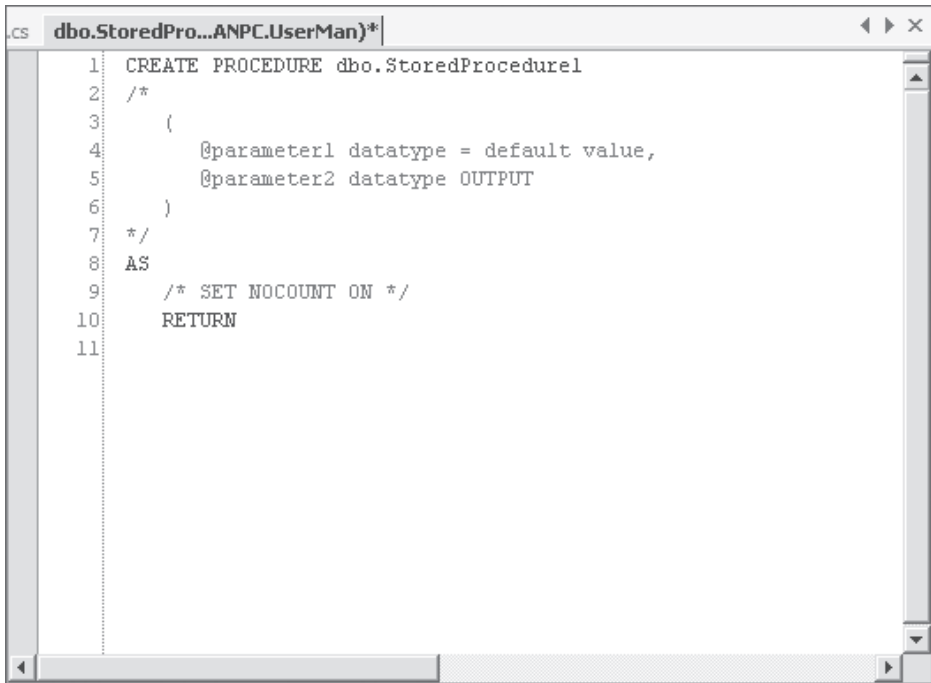

Figure 6-1. Stored procedure editor with SQL Server default template

**NOTE** With SQL Server it's only possible to use T-SQL for your stored procedures. However, the upcoming version of SQL Server, code-named Yukon, will have support for the .NET programming languages. Knowing this, perhaps you'll want to create your stored procedures in C# or VB .NET.

### Creating a Simple Stored Procedure

Once you've created a stored procedure, you need to give it a name. As you can see from your stored procedure editor, the template automatically names it `StoredProcedure1`. If you're wondering about the `dbo` prefix, it simply means that the stored procedure is created for the `dbo` user. In SQL Server terms, `dbo` stands for *database owner*, and it indicates who owns the database object, which is a stored procedure in this case. If you've been working with SQL Server for a while, you probably know the term *broken ownership chain*. An ownership chain is the dependency of a stored procedure upon tables, views, or other stored procedures.

Generally, the objects that a view or stored procedure depend on are also owned by the owner of the view or stored procedure. In such a case there are no problems, because SQL Server doesn't check permissions in this situation. (It doesn't really have to, does it?) However, when one or more of the dependent database objects are owned by a different user than the one owning the view or stored procedure, the ownership chain is said to be broken. This means that SQL Server has to check the permissions of any dependent database object that has a different owner. This can be avoided, if the same user, such as `dbo`, owns all of your database objects. I am not telling you to do it this way, but it's one option available to you.

Okay, let's say you've deleted the `StoredProcedure1` name and replaced it with `SimpleStoredProcedure`. To save the stored procedure before continuing, press `Ctrl+S`. If you saved your stored procedure at this point, you would notice that you don't have to name it using a `Save As` dialog box, because you've already named it. The editor will make sure that the stored procedure is saved on the database server with the name you've entered, which in this case is `SimpleStoredProcedure`. You shouldn't save it until you've renamed it, because you'll end up having to remove unwanted stored procedures.

Although you can see your stored procedure in the `Stored Procedure` folder of the `SQL Server Enterprise Manager` and the `Stored Procedure` node in the `Server Explorer`, there isn't actually an area in your database designated for just stored procedures. The stored procedure is saved to the system tables as are most other objects in `SQL Server`.

As soon as you have saved it, the very first line of the stored procedure changes. The `SQL` statement `CREATE PROCEDURE` is changed so that the first line reads:

```
ALTER PROCEDURE dbo.SimpleStoredProcedure
```

Why? Well, you just saved the newly created stored procedure, which means that you can't create another with the same name. Changing `CREATE` to `ALTER` takes care of that. It's that simple. In case you're wondering what happens when you change the name of your stored procedure and the `SQL` statement still reads `ALTER PROCEDURE . . .`, I can tell you: the editor takes care of it for you and creates a new procedure. Try it and see for yourself! Basically, this means that `CREATE PROCEDURE` is never actually needed; one can simply use `ALTER PROCEDURE`, even on brand new procedures. However, this can be a dangerous practice, if you inadvertently change the name of your stored procedure to the name of an already existing one.

The `SimpleStoredProcedure` doesn't actually do a lot, does it? Okay, let me show you how to change that. In `Figure 6-1`, you can see two parts of the stored procedure: The first part is the header and then there is the actual stored procedure itself. The header consists of all text down to and including `Line 7`. Basically,

the header declares how the stored procedure should be called, how many arguments to include and what type of arguments, and so on. Since this is a very simple procedure, I don't want any arguments, so I'll leave the commented-out text alone.

If you haven't changed the default editor settings, text that is commented out or any comments you have inserted yourself are printed in green. In a SQL Server stored procedure, comments are marked using start and end tags: `/*` for the comment start tag and `*/` for the comment end tag. This has one advantage over the way you insert comments in your C# code in that you don't have to have a comment start tag on every line you want to comment out. You only need to have both a start and end tag.

The second part of the stored procedure is the part that starts with the `AS` clause on Line 8. The `AS` clause indicates that the text that follows is the body of the stored procedure, the instructions on what to do when the stored procedure is called and executed.

## EXERCISE

- 1) Create a stored procedure, name it **SimpleStoredProcedure**, and save it as described earlier.
- 2) Type the following text on Line 10 in the `SimpleStoredProcedure` in place of the `RETURN` statement:

```
SELECT COUNT(*) FROM tblUser
```

Now the stored procedure should look like the example in Figure 6-2. The stored procedure will return the number of rows in the `tblUser` table. Please note that it's generally good practice to keep the `RETURN` statement as part of your stored procedure, but I'm taking it out and leaving it for an explanation later, when I discuss return values and how they're handled in code.

```

1 ALTER PROCEDURE dbo.SimpleStoredProcedure
2 /*
3 (
4     @parameter1 datatype = default value,
5     @parameter2 datatype OUTPUT
6 )
7 */
8 AS
9 /* SET NOCOUNT ON */
10 SELECT COUNT(*) FROM tblUser
11

```

Figure 6-2. Stored procedure that returns the number of rows in the `tblUser` table

3) Don't forget to save the changes using Ctrl+S.

---

### *Running a Simple Stored Procedure from the IDE*

Of course, there's no point in having a stored procedure that just sits there, so here's what you do to run it: if you have the stored procedure open in the stored procedure editor window, you can right-click anywhere in the editor window and select Run Stored Procedure from the pop-up menu. If you do this with the stored procedure you created in the exercise in the previous section, the Output window, located just below the editor window, should display the output from the stored procedure as shown in Figure 6-3.

Figure 6-3. The Output window with output from SimpleStoredProcedure

If you have closed down the stored procedure editor window, you can run the stored procedure from the Server Explorer. Expand the database node, right-click the Stored Procedures node, and select Run Stored Procedure from the pop-up menu. This will execute the stored procedure the exact same way as if you were running it from the editor window.

### Running a Simple Stored Procedure from Code

Okay, now that you have a fully functional stored procedure, you can try and run it from code. Listing 6-1 shows you some very simple code that will run the stored procedure. The example code in this listing uses data classes that were introduced in Chapters 3A and 3B.

#### Listing 6-1. Running a Simple Stored Procedure

```

1 public void ExecuteSimpleSP() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmmUser;
4     object objNumUsers;
5
6     // Instantiate and open the connection
7     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
8     cnnUserMan.Open();
9
10    // Instantiate and initialize command
11    cmmUser = new SqlCommand("SimpleStoredProcedure", cnnUserMan);
12    cmmUser.CommandType = CommandType.StoredProcedure;
13
14    objNumUsers = cmmUser.ExecuteScalar();
15    MessageBox.Show(objNumUsers.ToString());
16 }
  
```

The code in Listing 6-1 retrieves the return value from the stored procedure. Now, this isn't usually all you want from a stored procedure, but it merely demonstrates what a simple stored procedure looks like. The stored procedure itself could just as well have had a `DELETE FROM tblUser WHERE LastName='Johnson'` SQL statement. If you want to execute this from code, you need to know if the stored procedure returns a value or not. It doesn't in this case, so you need to use the `ExecuteNonQuery` method of the `SqlCommand` class.

## EXERCISE

- 1) Create a new stored procedure and save it with the name **uspGetUsers**.
- 2) Type in the following text on Line 10 in place of the RETURN statement:

**SELECT \* FROM tblUser**

Now the stored procedure should look like the one in Figure 6-4. This stored procedure will return all rows in the `tblUser` table.

```

1 ALTER PROCEDURE dbo.uspGetUsers
2 /*
3 {
4     @parameter1 datatype = default value,
5     @parameter2 datatype OUTPUT
6 }
7 */
8 AS
9     /* SET NOCOUNT ON */
10    SELECT * FROM tblUser
11

```

Figure 6-4. The `uspGetUsers` stored procedure

- 3) Don't forget to save the changes using `Ctrl+S`.

What you need now is some code to retrieve the rows from the stored procedure (see Listing 6-2).

*Listing 6-2. Retrieving Rows from a Stored Procedure*

```

1 public void ExecuteSimpleRowReturningSP() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmmUser;
4     SqlDataReader drdUser;
5
6     // Instantiate and open the connection
7     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
8     cnnUserMan.Open();
9
10    // Instantiate and initialize command
11    cmmUser = new SqlCommand("uspGetUsers", cnnUserMan);
12    cmmUser.CommandType = CommandType.StoredProcedure;
13
14    // Retrieve all user rows
15    drdUser = cmmUser.ExecuteReader();
16 }

```

The example in Listing 6-2 retrieves the rows returned from the stored procedure by using the **ExecuteReader** method of the **SqlCommand** class. Please note that this method and the related **ExecuteXmlReader** method are the only options for retrieving rows as the result of a function call with the Command class.

### *Creating a Stored Procedure with Arguments*

Sometimes it's a good idea to create a stored procedure with arguments<sup>3</sup> instead of having more stored procedures essentially doing the same. It also gives you some flexibility with regards to making minor changes to your application without having to recompile one or more parts of it, because you can add to the number of arguments and keep existing applications running smoothly by specifying a default value for the new arguments.

Another reason for using arguments with stored procedures is to make the stored procedure behave differently, depending on the input from the arguments. One argument might hold the name of a table, view, or another stored procedure to extract data from.

---

3. I'm using the word *argument* here, but I might as well call it *parameter*, like T-SQL does. However, the two words are synonymous in this case.

**TIP** In SQL Server you can use the `EXECUTE sp_executesql` statement and System Stored Procedure with arguments of type **ntext**, **nchar**, or **nvarchar** to execute parameterized queries. See the SQL Server Books Online Help Documentation for more information.

## EXERCISE

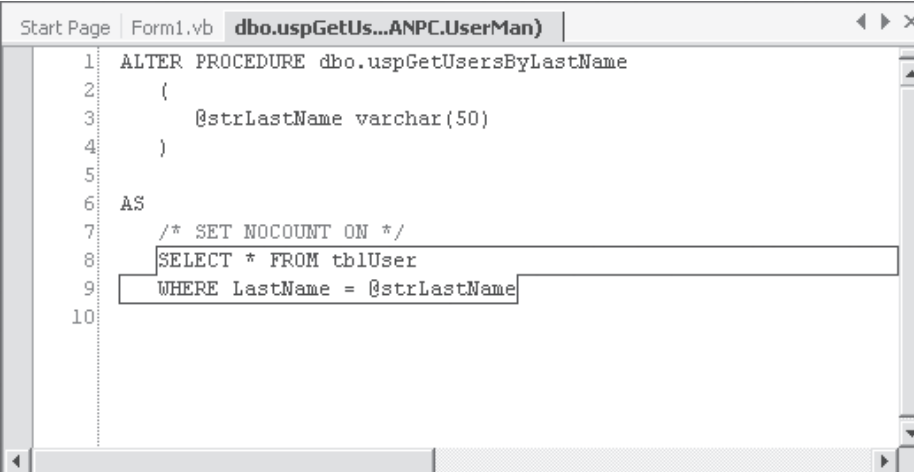

- 1) Create a new stored procedure and save it with the name **uspGetUsersByLastName**.
- 2) Type in the following text on Lines 10 and 11 in place of the RETURN statement:

```
SELECT * FROM tblUser
WHERE LastName = @strLastName
```

- 3) Uncomment Lines 2 to 7, and insert the following text instead of Lines 3 and 4:

```
@strLastName varchar(50)
```

The stored procedure should look like the one in Figure 6-5. This stored procedure will return all rows in the `tblUser` table where the `LastName` column matches the `strLastName` argument.

```

1 ALTER PROCEDURE dbo.uspGetUsersByLastName
2 (
3     @strLastName varchar(50)
4 )
5
6 AS
7 /* SET NOCOUNT ON */
8 SELECT * FROM tblUser
9 WHERE LastName = @strLastName
10

```

Figure 6-5. The `uspGetUsersByLastName` stored procedure

- 4) Don't forget to save your changes using `Ctrl+S`.

Arguments in stored procedures can be either input or output. If you include an input argument, you don't have to specify anything after the data type, but if you use an output argument, you need to specify the OUTPUT keyword after the data type.

**NOTE** *I only cover the absolute basics of how to create a stored procedure in this chapter. If you need more information, I suggest you look up the CREATE PROCEDURE statement in the Books Online help application that comes with SQL Server.*

### *Running a Stored Procedure with Arguments from the IDE*

Try and run the stored procedure you created in the last exercise and see how the argument affects how it's run. You can try running the stored procedure from either the editor window or the Server Explorer window. The Run dialog box asks you for a value for the `strLastName` argument. Type **Doe** in the text box and click OK. Now all users with the last name of Doe are returned as the result of the stored procedure.

### *Using a Stored Procedure with Arguments*

The `uspGetUsersByLastName` stored procedure seems to work, so try and run it from code. Listing 6-3 shows how you would do this.

#### *Listing 6-3. Retrieving Rows from a Stored Procedure with an Input Argument*

```
1 public void GetUsersByLastName() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmmUser;
4     SqlDataReader drdUser;
5     SqlParameter prmLastName;
6
7     // Instantiate and open the connection
8     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10
11    // Instantiate and initialize command
12    cmmUser = new SqlCommand("uspGetUsersByLastName", cnnUserMan);
13    cmmUser.CommandType = CommandType.StoredProcedure;
14    // Instantiate, initialize and add parameter to command
15    prmLastName = cmmUser.Parameters.Add("@strLastName", SqlDbType.VarChar,
16        50);
```

```

17 // Indicate this is an input parameter
18 prmLastName.Direction = ParameterDirection.Input;
19 // Set the value of the parameter
20 prmLastName.Value = "Doe";
21
22 // Return all users with a last name of Doe
23 drdUser = cmmUser.ExecuteReader();
24 }

```

In Listing 6-3, a **SqlParameter** object specifies the input parameter of the stored procedure. On Lines 15 and 16, I ask the command object to create and associate a parameter with the `@strLastName` argument. The value of this parameter is set to “Doe”, which effectively means that only rows containing a last name of Doe are returned.

As you can see, I have specified that the parameter is an input argument using the **ParameterDirection** enum, although you don’t really have to, because this is the default. Don’t worry too much about parameter and argument; they are essentially the same thing.

### *Creating a Stored Procedure with Arguments and Return Values*

So far I have created stored procedures that return a single value or a result set (rows) and a stored procedure that takes an input argument. In many cases, this is all you want, but sometimes it’s not enough. What if you want a value and a result set returned at the same time? Actually, you may want several values and a result set, but I’m sure you get the idea. In such instances, you can use output arguments.

Actually, you can return as many different values and result sets as you want by including multiple **SELECT** statements after the **AS** clause, but I personally think this approach looks messy. If I return rows and one or more values, I generally use **OUTPUT** arguments for the values. I guess to some extent this is a matter of preference. However, you should be aware that including an output parameter is a faster approach than having it returned in a **DataSet** object, but sometimes you might need the richer functionality of the **DataSet** class, once the values have been returned.

Instead of using the following example code to return a scalar value, two result sets, and another scalar value in that order:

```

...
AS
    SELECT 19
    SELECT * FROM tblUser
    SELECT * FROM tblUserRights
    SELECT 21

```

I would use something like this:

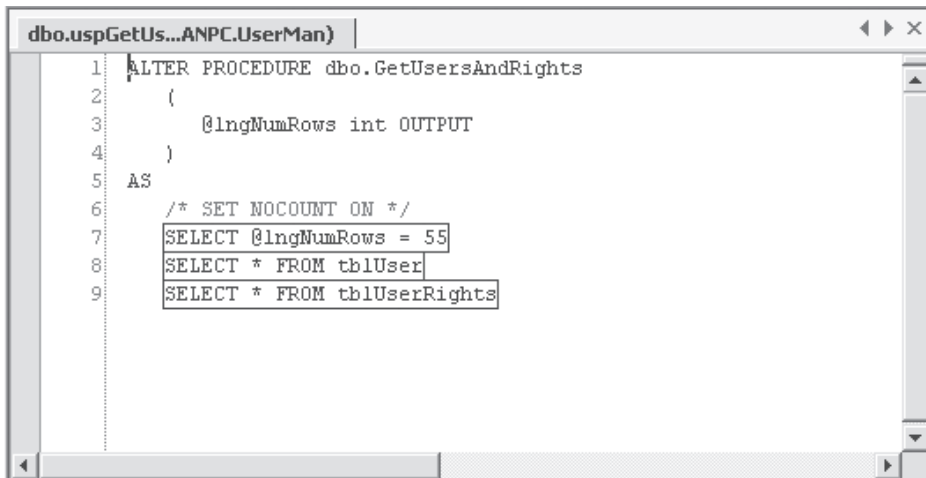

```
...
AS
    SELECT * FROM tblUser
    SELECT * FROM tblUserRights
```

The two return values should then be returned as OUTPUT arguments. But it's your call, my friend, as to which approach you prefer to use. Please note that OUTPUT arguments can also serve as INPUT arguments by default, meaning you can actually supply a value in the OUTPUT argument when calling the stored procedure, and get a different value back. Just like a value passed by reference from one procedure to another.

## EXERCISE

Create a new stored procedure and save it with the name **uspGetUsersAndRights**. This stored procedure should return the value 55 for the OUTPUT argument `lngNumRows`, and then all rows in the `tblUser` table and all rows in the `tblUserRights` table.

The stored procedure should look like the one in Figure 6-6.

```
dbo.uspGetUs...ANPC.UserMan)
1 ALTER PROCEDURE dbo.GetUsersAndRights
2   (
3     @lngNumRows int OUTPUT
4   )
5 AS
6   /* SET NOCOUNT ON */
7   SELECT @lngNumRows = 55
8   SELECT * FROM tblUser
9   SELECT * FROM tblUserRights
```

Figure 6-6. The `uspGetUsersAndRights` stored procedure

In the `uspGetUsersAndRights` stored procedure, shown in Figure 6-6, you can see that the `@lngNumRows int` argument is set to the value 55 on Line 7. However, using a default value for the argument you can achieve the same result, by changing Line 3 like this:

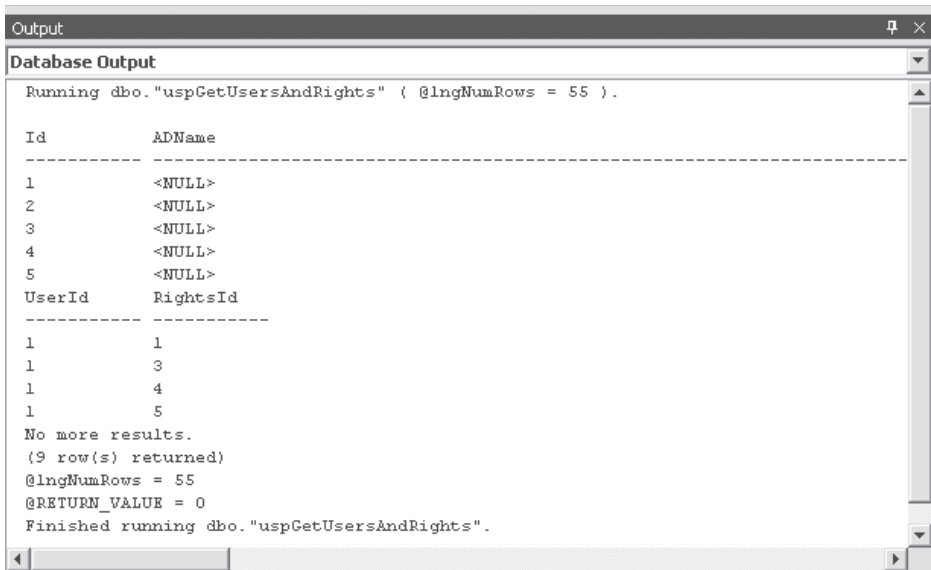

```
@lngNumRows int = 55 OUTPUT
```

This means that if for some reason you don't set the value of this parameter when calling the stored procedure or within the stored procedure itself, it'll return 55 as the output value. Default argument values also work for input arguments, and they're specified the same way, using the equal sign followed by the default value, right after the data type.

### *Running a Stored Procedure with Arguments and Return Values from the IDE*

If you've created and saved the stored procedure in the previous exercise, test it by running it. You can try running the stored procedure from either the editor window or the Server Explorer window. The Output window, located just below the editor window, will display the output from the stored procedure, and it should look similar to the output in Figure 6-7.

**NOTE** *Syntax testing of your stored procedure is done when you save it, and I have a feeling you have already encountered this. If not, just know that's how it is—syntax errors are caught when you try to save your stored procedure.*

```

Output
-----
Database Output
Running dbo."uspGetUsersAndRights" ( @lngNumRows = 55 ).

Id          ADName
-----
1           <NULL>
2           <NULL>
3           <NULL>
4           <NULL>
5           <NULL>
UserId      RightsId
-----
1           1
1           3
1           4
1           5
No more results.
(9 row(s) returned)
@lngNumRows = 55
@RETURN_VALUE = 0
Finished running dbo."uspGetUsersAndRights".

```

Figure 6-7. The Output window with output from the `uspGetUsersAndRights` stored procedure

### Using a Stored Procedure with Arguments and Return Values

Listing 6-4 shows the code to execute the `uspGetUsersAndRights` stored procedure programmatically.

#### Listing 6-4. Retrieving Rows and Output Values from a Stored Procedure

```

1 public void GetUsersAndRights() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmmUser;
4     SqlDataReader drdUser;
5     SqlParameter prmNumRows;
6
7     // Instantiate and open the connection
8     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10
11    // Instantiate and initialize command
12    cmmUser = new SqlCommand("uspGetUsersAndRights", cnnUserMan);
13    cmmUser.CommandType = CommandType.StoredProcedure;
14    // Instantiate, initialize and add parameter to command
15    prmNumRows = cmmUser.Parameters.Add("@lngNumRows", SqlDbType.Int);
16    // Indicate this is an output parameter

```

```

17     prmNumRows.Direction = ParameterDirection.Output;
18     // Get first batch of rows (users)
19     drdUser = cmmUser.ExecuteReader();
20
21     // Display the last name of all user rows
22     while (drdUser.Read()) {
23         MessageBox.Show(drdUser["LastName"].ToString());
24     }
25
26     // Get next batch of rows (user rights)
27     if (drdUser.NextResult()) {
28         // Display the id of all rights
29         while (drdUser.Read()) {
30             MessageBox.Show(drdUser["RightsId"].ToString());
31         }
32     }
33 }

```

In Listing 6-4, two result sets are returned, and therefore I use the **NextResult** method of the `DataReader` class to advance to the second result set on Line 27. Otherwise this stored procedure works pretty much the same as one with input parameters, although the parameter direction is specified as an output on Line 17.

### *Retrieving a Value Specified with RETURN*

In a stored procedure, you can use the `RETURN` statement to return a scalar value. However, this value cannot be retrieved using the **ExecuteScalar** method of the `Command` class, as it would when you use the `SELECT` statement (refer back to Figure 6-2). Of course there is a way of retrieving this value, which I show you after the following exercise.

## EXERCISE

Create a new stored procedure and save it with the name **uspGetRETURN\_VALUE**. This stored procedure should return the value 55 as the RETURN\_VALUE. The stored procedure should look like the one in Figure 6-8.

```

1 ALTER PROCEDURE dbo.uspGetRETURN_VALUE
2 /*
3 {
4     @parameter1 datatype = default value,
5     @parameter2 datatype OUTPUT
6 }
7 */
8 AS
9 /* SET NOCOUNT ON */
10 RETURN 55
11

```

Figure 6-8. The uspGetRETURN\_VALUE stored procedure

Listing 6-5 shows you how to retrieve the value from code.

*Listing 6-5. Retrieving RETURN\_VALUE from a Stored Procedure*

```

1 public void GetRETURN_VALUE() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmdUser;
4     SqlParameter prmNumRows;
5     object objResult;
6
7     // Instantiate and open the connection
8     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10

```

```

11 // Instantiate and initialize command
12 cmmUser = new SqlCommand("uspGetRETURN_VALUE", cnnUserMan);
13 cmmUser.CommandType = CommandType.StoredProcedure;
14 // Instantiate, initialize and add parameter to command
15 prmNumRows = cmmUser.Parameters.Add("@RETURN_VALUE", SqlDbType.Int);
16 // Indicate this is a return value parameter
17 prmNumRows.Direction = ParameterDirection.ReturnValue;
18 // Get RETURN_VALUE like this, ...
19 objResult = cmmUser.ExecuteScalar();
20 // or like this
21 MessageBox.Show(prmNumRows.Value.ToString());
22 }

```

In Listing 6-5, the **ExecuteScalar** method gets the RETURN\_VALUE from a stored procedure. Normally, you would use this method to return the value in the `lngResult` variable, but this variable will contain the default value, 0, in this case. However, because I have specified the **Direction** property of the `prmNumRows` parameter with the **ReturnValue** member of the **ParameterDirection** enum, I can simply look at the **Value** property of the parameter after executing the command.

## *Changing the Name of a Stored Procedure*

If you change the name of your stored procedure in the editor window, the stored procedure is saved with the new name when you save (Ctrl+S). However, if you're not using this method to copy an existing stored procedure, you should be aware that the old stored procedure still exists. So you'll have to delete it if you don't want it.

## *Viewing Stored Procedure Dependencies*

In SQL Server Enterprise Manager, you can see what tables and other objects your stored procedure uses or is dependent on. Open up Enterprise Manager, expand your SQL Server, expand databases and your database, select the Stored Procedures node, right-click the stored procedure you want to see the dependencies for, and select All Task Display Dependencies from the pop-up menu. This brings up the Dependencies dialog box, where you can see what database objects your stored procedure depends on and vice versa. This is also called the *ownership chain*.

## Running Oracle Stored Procedures

Oracle stored procedures and stored functions are different from those of SQL Server. That's why I've chosen to explain the Oracle stored procedures in a separate section. When discussing what you can do with stored procedures/functions in Oracle compared to stored procedures in SQL Server, it's pretty much the same, but the implementation is quite different.

SQL Server stored procedures can return a value, just like a function in C#, whereas in Oracle you have stored procedures and stored functions. This means that if you want a return value that isn't a parameter, you must use a stored function. In this chapter, you won't see how to create stored procedures and stored functions in Oracle, but you can use the Oracle Database Project located in the example code, which you can download from the Apress Web site (<http://www.apress.com>) or the UserMan site (<http://www.userman.dk>), to create the tables, stored procedures, views, and triggers used by the Oracle example code. Please consult your Oracle documentation if you need more information on how to implement stored procedures and stored functions in Oracle.

When you use ADO.NET and ADO for that matter, you can't use the **ExecuteScalar** method of the `DataReader` class to retrieve a return value, as shown in Listings 6-1 and 6-5 and discussed in the "Retrieving a Value Specified with RETURN" section. This is also true if you execute a stored function. You need to return any return values in output parameters, just as I've demonstrated in Listing 6-4. If you only need to return a value, as in Listing 6-1, which is what the Oracle stored function in Listing 6-6 does, you can do as is shown in Listing 6-7, which is really more or less the same code as in Listing 6-1.

### *Listing 6-6. A Simple Oracle Stored Function*

```
1 CREATE OR REPLACE FUNCTION SIMPLESTOREDFUNCTION
2 RETURN NUMBER
3 AS
4   lngNumRows NUMBER;
5 BEGIN
6   SELECT COUNT(*) INTO lngNumRows FROM TBLUSER;
7   RETURN lngNumRows;
8 END SIMPLESTOREDFUNCTION;
```

In Listing 6-6, you can see an Oracle stored function that returns the number of rows in the `tblUser` table. You can see in Listing 6-7 how you can access this stored function and retrieve the return value.

*Listing 6-7. Running a Simple Oracle Stored Function*

```

1 public void ExecuteSimpleOracleSF() {
2     OleDbConnection cnnUserMan;
3     OleDbCommand cmmUser;
4     OleDbParameter prmNumRows;
5     object objReturnValue;
6
7     // Instantiate and open the connection
8     cnnUserMan = new OleDbConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10
11    // Instantiate and initialize command
12    cmmUser = new OleDbCommand("SimpleStoredFunction", cnnUserMan);
13    cmmUser.CommandType = CommandType.StoredProcedure;
14    // Instantiate output parameter and add to parameter
15    // collection of command object
16    prmNumRows = cmmUser.CreateParameter();
17    prmNumRows.Direction = ParameterDirection.ReturnValue;
18    prmNumRows.DbType = DbType.Int64;
19    prmNumRows.Precision = 38;
20    prmNumRows.Size = 38;
21    cmmUser.Parameters.Add(prmNumRows);
22
23    // Retrieve and display value
24    objReturnValue = cmmUser.ExecuteScalar();
25    MessageBox.Show(cmmUser.Parameters[0].Value.ToString());
26 }

```

In Listing 6-7, I've actually used the **ExecuteScalar** method of the `DataReader` class on Line 24, but if you look carefully, you'll see that I don't use the value returned from the function call (`objReturnValue`) as in Listing 6-1. However, I do retrieve the return value in the `prmNumRows` parameter, which is instantiated, initialized, and set up as a return value on Lines 12 through 21, and display it after executing the command on Line 25. I use **ExecuteScalar** method, because it has the least overhead of any of the **Execute** methods of the `DataReader` class. So even if you don't use the return value from the **ExecuteScalar** method, which is always **null** when calling an Oracle stored function or stored procedure, you can still get the return value from the stored function. The trick is add a parameter to the command object and make sure you set the **Direction** property of the parameter object to the **ReturnValue** member of the **ParameterDirection** enum, as is shown on Line 13.

If you want to use an Oracle stored procedure instead of a stored function, like the one shown in Listing 6-8, to retrieve one or more simple data types using output parameters, you can use the example code shown in Listing 6-9.

*Listing 6-8. A Simple Oracle Stored Procedure*

```
1 CREATE OR REPLACE PROCEDURE SIMPLESTOREDPROCEDURE
2 (lNgNumRows OUT NUMBER)
3 AS
4 BEGIN
5     SELECT COUNT(*) INTO lNgNumRows FROM TBLUSER;
6 END SIMPLESTOREDPROCEDURE;
```

The Oracle stored procedure in Listing 6-8 accepts one output parameter (`lNgNumRows`) and sets this parameter to the number of rows in the `tblUser` table when executed. You can see how you can call this stored procedure from code, in Listing 6-9.

*Listing 6-9. Running a Simple Oracle Stored Procedure*

```
1 public void ExecuteSimpleOracleSP() {
2     OleDbConnection cnnUserMan;
3     OleDbCommand cmmUser;
4     OleDbParameter prmNumRows;
5     object objReturnValue;
6
7     // Instantiate and open the connection
8     cnnUserMan = new OleDbConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10
11    // Instantiate and initialize command
12    cmmUser = new OleDbCommand("SimpleStoredProcedure", cnnUserMan);
13    cmmUser.CommandType = CommandType.StoredProcedure;
14    // Instantiate output parameter and add to parameter
15    // collection of command object
16    prmNumRows = cmmUser.CreateParameter();
17    prmNumRows.Direction = ParameterDirection.Output;
18    prmNumRows.DbType = DbType.Int64;
19    prmNumRows.Precision = 38;
20    prmNumRows.Size = 38;
21    cmmUser.Parameters.Add(prmNumRows);
22
23    // Retrieve and display value
24    objReturnValue = cmmUser.ExecuteScalar();
25    MessageBox.Show(cmmUser.Parameters[0].Value.ToString());
26 }
```

In Listing 6-9, I again use the **ExecuteScalar** method of the `DataReader` class on Line 24 for retrieving a value from a stored procedure. The example code on Listing 6-9 really isn't all that different from Listing 6-7, but it does show you how to call a stored procedure instead of a stored function.

The Oracle stored procedures and stored functions, and the example code to execute them shown so far, only deal with simple return values. If you need to return result sets, such as in Listings 6-2, 6-3, and 6-4, you need to use cursors in the stored procedures.<sup>4</sup> Listing 6-10 shows a stored procedure that returns a result set using cursors.

*Listing 6-10. Oracle Stored Procedure Returning Result Set*

```

1 CREATE OR REPLACE PACKAGE PKGTBLUSER
2 AS
3     TYPE CUR_TBLUSER IS REF CURSOR RETURN TBLUSER%ROWTYPE;
4 END PKGTBLUSER;
5
6 CREATE OR REPLACE PROCEDURE USPGETUSERSBYLASTNAME
7     (ROWS OUT PKGTBLUSER.CUR_TBLUSER, strLastName IN VARCHAR2)
8 IS
9 BEGIN
10 OPEN ROWS FOR SELECT * FROM TBLUSER
11 WHERE LASTNAME = strLastName;
12 END USPGETUSERSBYLASTNAME;
```

In Listing 6-10, you can see how I first create a package definition (Lines 1 through 4) in my Oracle database, and in this package I define the `CUR_TBLUSER` cursor type, which is of data type **REF CURSOR**,<sup>5</sup> that returns rows from the `tblUser` table. The package definition only holds the type declaration, which is used in the stored procedure. Please note that the notion of Oracle package definitions and package bodies are beyond the scope of this book, although you can certainly use a package body instead of the stored procedure shown on Lines 6 through 12. Please see your Oracle documentation for more information on packages.

You need to declare the cursor type in a package, because you're using it as the data type for one of the parameters in the `USPGETUSERSBYLASTNAME` stored procedure. You can't declare a data type in the parameters section of a stored

- 
4. You can also use cursors with a stored function, but because I won't be using the function return value from this point on, I'll concentrate on using stored procedures.
  5. This is short for REFERENCE CURSOR, and basically it's used as a pointer to the original data. Please see your Oracle documentation for more information.

procedure, which is why you need it declared elsewhere. If you look at the parameters declaration on Line 7, you can see that I need to use the full path to the data type, PKGTBLUSER.CUR\_TBLUSER. Lines 10 and 11 of Listing 6-10 is where the rows that match the passed last name criterion, are retrieved with the CUR\_TBLUSER cursor and saved in the ROWS OUT parameter. Listing 6-11 shows you how to retrieve the result set from the stored procedure.

*Listing 6-11. Retrieving Result Set from Oracle Stored Procedure*

```

1 public void OracleGetUsersByLastName() {
2     OleDbConnection cnnUserMan;
3     OleDbCommand cmmUser;
4     OleDbParameter prmLastName;
5     OleDbDataReader drdUser;
6
7     // Instantiate and open the connection
8     cnnUserMan = new OleDbConnection(STR_CONNECTION_STRING);
9     cnnUserMan.Open();
10
11    // Instantiate and initialize command
12    cmmUser = new OleDbCommand("USPGETUSERSBYLASTNAME", cnnUserMan);
13    cmmUser.CommandType = CommandType.StoredProcedure;
14    // Instantiate, initialize and add parameter to command
15    prmLastName = cmmUser.Parameters.Add("strLastName", OleDbType.VarChar,
16        50);
17    // Indicate this is an input parameter
18    prmLastName.Direction = ParameterDirection.Input;
19    // Set the type and value of the parameter
20    prmLastName.Value = "Doe";
21
22    // Retrieve rows
23    drdUser = cmmUser.ExecuteReader();
24    // Loop through the returned rows
25    while (drdUser.Read()) {
26        // Display the last name of all user rows
27        MessageBox.Show(drdUser["LastName"].ToString());
28    }
29 }

```

In Listing 6-11, you can see how I set up the command object on Lines 12 through 13, and then prepare the prmLastName input parameter with the value of “Doe”. I then call the **ExecuteReader** method of the Command class, which returns the DataReader with all users with a last name of Doe. If you compare the stored procedure in Listing 6-10 and the example code in Listing 6-11, you’ll see

that there's a mismatch of the number of parameters. The stored procedure has two parameters, the last name input parameter and the result set output parameter. However, I only set up one parameter in Listing 6-11 and that's the last name input parameter. The command object takes care of returning the result set as the return value of the function call (**ExecuteReader**) instead of as an output parameter. It almost works the same as with the SQL Server example code in Listing 6-3.

**NOTE** *It doesn't matter where you place the `ROWS OUT` parameter in the stored procedure parameter declaration—that is, whether you place it first as is done in Listing 6-10, or last like this:*

```
(strLastName IN VARCHAR2, ROWS OUT PKGTBLUSER.CUR_TBLUSER)
```

There are other ways of calling a stored procedure in your Oracle database, such as using the ODBC {call storedprocedurename} syntax, but I've chosen to show you the way that looks and feels as close to the one used for calling SQL Server procedures.

## Using Views

A *view* is, as the word suggests, a display of data in your database. Perhaps it helps to think of a view as a virtual table. It can be a subset of a table or an entire table, or it can be a subset of several joined tables. Basically, a view can represent just about any subset of data in your database, and you can include other views in a view. Including a view in another view is called *nesting*, and it can be a valuable way of grouping display data. However, nesting too deeply can also result in performance problems and can certainly make it a real challenge to track down errors. There isn't really any magic to a view or any big secrets that I can let you in on; it's simply just a great tool for manipulating your data. In the rest of this section, I am going to look at why, when, where, and how you should use a view.

**NOTE** *The example code shown in this section is SQL Server only, but if you take a look at the accompanying example code, you'll see that it works exactly the same with Microsoft Access queries. Only the SQL Server .NET Data Provider has been changed to the OLE DB .NET Data Provider. The same goes for Oracle views. See the example code, which is almost identical to the Microsoft Access code. Views aren't supported in MySQL 3.23.45.*

## View Restrictions

A view is almost identical to a row-returning query, with just a few exceptions. Some of the restrictions are detailed here:

- COMPUTE and COMPUTE BY clauses cannot be included in your view.
- ORDER BY clauses aren't allowed in a view, unless you specify the TOP clause as part of the SELECT statement. However, you can index a view with SQL Server 2000.
- The INTO keyword cannot be used to create a new table.
- Temporary tables cannot be referenced.

There are other restrictions, so please check with your SQL Server documentation and/or Help Files.

## Why Use a View?

Like stored procedures, views are used for server-side processing of your data, but whereas stored procedures mainly are used for security and performance reasons, views are generally used to secure access to your data and to hide complexity of queries that contain many joins. You may want to use a view for a variety of reasons:

- *Security:* You don't want your users to access the tables directly, and with the help of a view you can restrict users to seeing only the parts of a table they are allowed to see. You can restrict access to specific columns and/or rows and thus make it easy for your users to use for their own queries.
- *Encryption:* You can encrypt a view so that no one can see where the underlying data comes from. Mind you, this is an irreversible action, meaning that the textual SQL statements that form the view can't be retrieved again!
- *Aggregated data:* Views are often used on large scale systems to provide aggregated data.

There are other reasons for creating a view, but the mentioned reasons are certainly two of the most common.

## Creating a View

It's easy to create a view. If you are used to working with the SQL Server's **Server Manager**, you should check out what the **Server Explorer** has to offer you. Here's how you create a view using the UserMan database as an example:

1. Open up the Server Explorer window.
2. Expand the UserMan database on your database server.
3. Right-click the Views node and select New View.

This brings up the View Designer, which in fact is the same as the Query Designer.

**NOTE** *The Query Designer is described in detail in Chapter 4. Although the View Designer and Query Designer have the same look and feel, you cannot create views that don't adhere to the view restrictions mentioned in the section, "View Restrictions."*

The Add Table dialog box is also shown when the View Designer is displayed. In this dialog box, simply select the tables you want to retrieve data from and click Add. Click Close when all the required tables have been added.

As you start selecting in the Diagram pane the columns that should be output when the view is run, the SQL pane and the Grid pane change accordingly. When you are done selecting the columns to output, you should save the view using Ctrl+S.

## EXERCISE

- 1) Create a new view. This view should contain the following tables: tblUser, tblRights, and tblUserRights. The following fields should be output: tblUser.LoginName, tblUser.FirstName, tblUser.LastName, and tblRights.Name.
- 2) Save the view under the name **viwUserInfo**. The new view should look like the one in Figure 6-9.

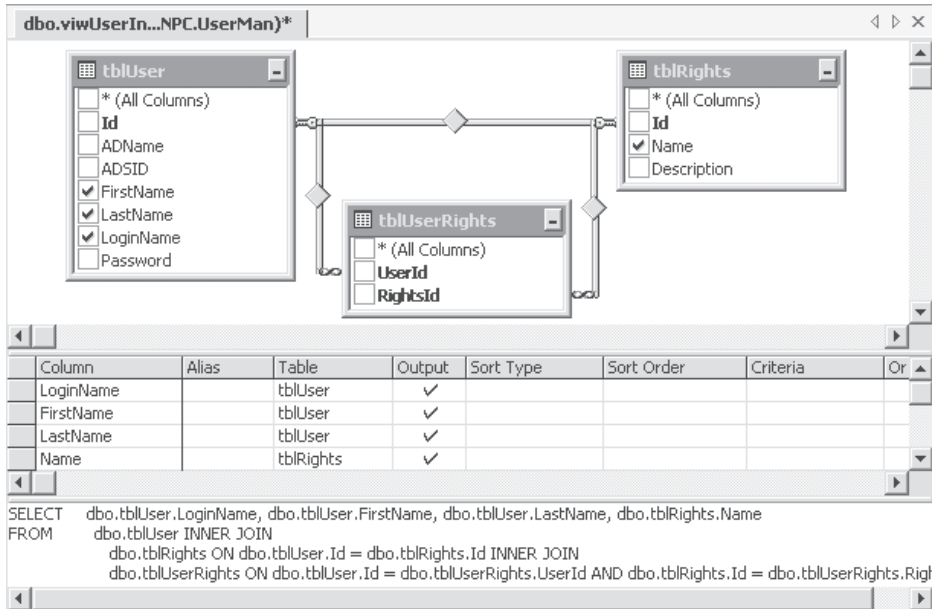

Figure 6-9. The `viwUserInfo` view

## Running a View from the IDE

“Running a view” is perhaps not the most appropriate phrase when you think about it. On the other hand, the view does have to retrieve the data from all the tables referenced in the view, so I guess this phrase will have to do.

Anyway, you can run a view from the View Designer by right-clicking a blank area of the View Designer and selecting Run from the pop-up menu. The data retrieved by the view is then displayed in the Results pane of the View Designer.

## EXERCISE

- 1) Run the `vwUserInfo` view from the View Designer. The Results pane now displays rows like the ones in Figure 6-10.

	LoginName	FirstName	LastName	Name
▶	UserMan	John	Doe	AddUser
*				

Figure 6-10. The results of running the `vwUserInfo` view

- 2) Notice that the Name field of the `tblRights` table seems a bit confusing, because it doesn't really show what Name means. So in the Grid pane, you should add the text **RightsName** to the Alias column in the Name row.
- 3) Run the view again and notice how the new column name appears in the Results pane.
- 4) Save the view with `Ctrl+S`.

## Using a View from Code

Actually, it's very easy to use a view in code, because a view is referenced like any standard table in your database, which means that you can retrieve data using a command object or a data adapter that fills a data set, and so on.

**NOTE** Please see Chapter 3B for specific information on how to manipulate data in a table.

### Retrieving Read-Only Data from a View in Code

The simplest use of a view is for display purposes, like when you just need to display some information from one or more related tables. Because in the example code I don't have to worry about updates, I don't have to set up anything particular. Listing 6-12 demonstrates how to return all rows from a view and populate a data reader.

*Listing 6-12. Retrieving Rows in a View*

```
1 public void RetrieveRowsFromView() {
2     SqlConnection cnnUserMan;
3     SqlCommand cmmUser;
4     SqlDataReader drdUser;
5
6     // Instantiate and open the connection
7     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
8     cnnUserMan.Open();
9
10    // Instantiate and initialize command
11    cmmUser = new SqlCommand("SELECT * FROM viwUserInfo", cnnUserMan);
12    // Get rows
13    drdUser = cmmUser.ExecuteReader();
14 }
```

Listing 6-12 is just like any other row-returning query, except that a view is queried instead of a table.

*Manipulating Data in a View from Code*

Listing 6-12 shows you how to retrieve data from a view into a data reader, and this means the data cannot be updated, because the data reader doesn't allow updates. However, it's possible to update data in a view. The problem with this is that various versions of SQL Server support different levels of update support for views. If you only have one table in a view, this isn't a problem at all; however, if you have multiple tables in a view, only SQL Server 2000 supports updating rows in more than one of the source tables. Besides the mentioned problems, you'll certainly run into even bigger problems if you need to migrate to a different RDBMS. Generally, I would discourage updating data in views.

## EXERCISE

- 1) Create a new view. This view should contain the tblUser table. The following fields should be output: Id, FirstName, LastName, and LoginName.
- 2) Save the view under the name **viwUser**. The new view should look like the one in Figure 6-11.

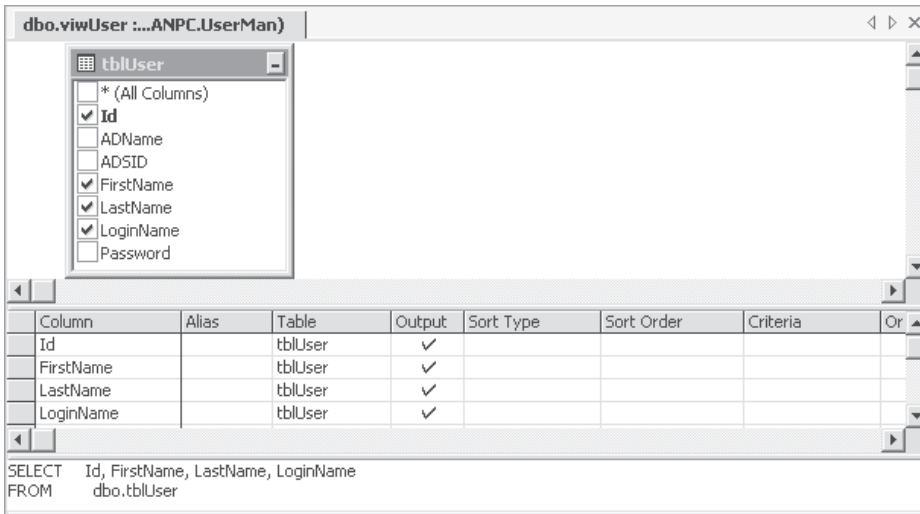

Figure 6-11. The viwUser view

This view, which can be located on SQL Server 7.0 as well as SQL Server 2000, can be manipulated using the code in Listing 6-13.

*Listing 6-13. Manipulating Data in a View Based on a Single Table*

```
1 public void ManipulatingDataInViewBasedOnSingleTable() {
2     const string STR_SQL_USER_SELECT = "SELECT * FROM viwUser";
3     const string STR_SQL_USER_DELETE = "DELETE FROM viwUser WHERE Id=@Id";
4     const string STR_SQL_USER_INSERT = "INSERT INTO viwUser(FirstName, " +
5         "LastName, LoginName, Logged, Description) VALUES(@FirstName, " +
6         "@LastName, @LoginName)";
7     const string STR_SQL_USER_UPDATE = "UPDATE viwUser SET FirstName=" +
8         "@FirstName, LastName=@LastName, LoginName=@LoginName WHERE Id=@Id";
9
10    SqlConnection cnnUserMan;
11    SqlCommand cmmUser;
```

```
12     SqlDataAdapter dadUser;
13     DataSet dstUser;
14
15     SqlCommand cmmUserSelect;
16     SqlCommand cmmUserDelete;
17     SqlCommand cmmUserInsert;
18     SqlCommand cmmUserUpdate;
19
20     SqlParameter prmSQLDelete, prmSQLUpdate;
21
22     // Instantiate and open the connection
23     cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
24     cnnUserMan.Open();
25
26     // Instantiate and initialize command
27     cmmUser = new SqlCommand("SELECT * FROM viwUser", cnnUserMan);
28     // Instantiate the commands
29     cmmUserSelect = new SqlCommand(STR_SQL_USER_SELECT, cnnUserMan);
30     cmmUserDelete = new SqlCommand(STR_SQL_USER_DELETE, cnnUserMan);
31     cmmUserInsert = new SqlCommand(STR_SQL_USER_INSERT, cnnUserMan);
32     cmmUserUpdate = new SqlCommand(STR_SQL_USER_UPDATE, cnnUserMan);
33     // Instantiate command and data set
34     cmmUser = new SqlCommand(STR_SQL_USER_SELECT, cnnUserMan);
35     dstUser = new DataSet();
36
37     dadUser = new SqlDataAdapter();
38     dadUser.SelectCommand = cmmUserSelect;
39     dadUser.InsertCommand = cmmUserInsert;
40     dadUser.DeleteCommand = cmmUserDelete;
41     dadUser.UpdateCommand = cmmUserUpdate;
42
43     // Add parameters
44     prmSQLDelete = dadUser.DeleteCommand.Parameters.Add("@Id", SqlDbType.Int,
45         0, "Id");
46     prmSQLDelete.Direction = ParameterDirection.Input;
47     prmSQLDelete.SourceVersion = DataRowVersion.Original;
48
49     cmmUserUpdate.Parameters.Add("@FirstName", SqlDbType.VarChar, 50,
50         "FirstName");
51     cmmUserUpdate.Parameters.Add("@LastName", SqlDbType.VarChar, 50,
52         "LastName");
53     cmmUserUpdate.Parameters.Add("@LoginName", SqlDbType.VarChar, 50,
54         "LoginName");
```

```

55     prmSQLUpdate = dadUser.UpdateCommand.Parameters.Add("@Id", SqlDbType.Int,
56         0, "Id");
57     prmSQLUpdate.Direction = ParameterDirection.Input;
58     prmSQLUpdate.SourceVersion = DataRowVersion.Original;
59
60     cmmUserInsert.Parameters.Add("@FirstName", SqlDbType.VarChar, 50,
61         "FirstName");
62     cmmUserInsert.Parameters.Add("@LastName", SqlDbType.VarChar, 50,
63         "LastName");
64     cmmUserInsert.Parameters.Add("@LoginName", SqlDbType.VarChar, 50,
65         "LoginName");
66
67     // Populate the data set from the view
68     dadUser.Fill(dstUser, "viwUser");
69
70     // Change the last name of user in the second row
71     dstUser.Tables["viwUser"].Rows[1]["LastName"] = "Thomsen";
72     dstUser.Tables["viwUser"].Rows[1]["FirstName"] = "Carsten";
73     // Propagate changes back to the data source
74     dadUser.Update(dstUser, "viwUser");
75 }

```

In Listing 6-13, a data adapter and a data set were set up to retrieve and hold data from the `viwUser` view. The `LastName` column of row 2 is then updated as well as the data source with the changes in the data set. This simple demonstration was designed to show you how to work with views based on a single table.

## Using Triggers

A *trigger* is actually a stored procedure that automatically invokes (triggers) when a certain change is applied to your data. Triggers are the final server-side processing functionality that I'll discuss in this chapter. Until SQL Server 2000 was released, triggers were a vital part of enforcing referential integrity, but with the release of SQL Server 2000, you now have that capability built in. In the rest of this section, I'll show you what a trigger is and when and how you can use it, but there is little C# programming involved with using triggers, because they operate entirely internally, only passing status or error indicators back to the client.

Triggers respond to data modifications using `INSERT`, `UPDATE`, and `DELETE` operations. Basically, you can say that a trigger helps you write less code; you can incorporate business rules as triggers and thus prevent the inclusion of data that is invalid because it violates your business rules.

SQL Server implements AFTER triggers, meaning that the trigger is invoked after the modification has occurred. However, this doesn't mean that a change can't be rolled back, because the trigger has direct access to the modified row and as such can roll back any modification. When SQL Server 2000 was released you also got support for the notion of BEFORE triggers, which you might know from the Oracle RDBMS. In SQL Server 2000, they are called INSTEAD OF triggers.

**NOTE** *The example code shown in this section is SQL Server only, but if you take a look at the accompanying example code, you'll see that Oracle after triggers work almost the same as SQL Server triggers, although the syntax is different. Only the SQL Server .NET Data Provider has been changed to the OLE DB .NET Data Provider. Triggers aren't supported in Microsoft Access or MySQL 3.23.45.*

### *Why Use a Trigger?*

Triggers are automatic, so you don't have to apply the business logic in your code. Here's a perfect situation for a business rule: you need to check if a member of an organization has paid his or her annual fee and therefore is allowed to order material from the organization's library. An INSERT trigger could perform the lookup in the members table when a member tries to order material and check if the member has paid the annual fee. This is exactly what makes a trigger more useful than a constraint in some situations, because a trigger can access columns in other tables, unlike a constraint, which can only access columns in the current table or row. If your code is to handle your business rule, this would mean that you need to look up the member's information in the members table before you can insert the order in the orders table. With the trigger, this lookup is done automatically, and an exception is thrown if you try to insert an order for library material if the member hasn't paid his or her annual fee. Furthermore, you don't have to rely on another front-end code developer to know what the business rules are.

In short, use a trigger for keeping all your data valid or to comply with your business rules. Think of triggers as an extra validation tool, while at the same time making sure you have set up referential integrity.

**NOTE** *With SQL Server 2000, you shouldn't use triggers for referential integrity (see Chapter 2), because you can set that up with the Database Designer. See Chapter 4 for information on the Database Designer.*

## Creating a Trigger

It's quite easy to create a trigger. This can be done using the Server Manager that comes with SQL Server, but I'll use the Server Explorer. Here's how you create a trigger for the example UserMan database:

1. Open up the Server Explorer window.
2. Expand the UserMan database on your database server.
3. Expand the Tables node.
4. Right-click the table for which you want to create a trigger and select New Trigger from the pop-up menu.

This brings up the trigger text editor, which is more or less the same editor you use for your C# code (see Figure 6-12).

```

1 CREATE TRIGGER tblUser_Trigger1
2 ON dbo.tblUser
3 FOR /* INSERT, UPDATE, DELETE */
4 AS
5     /* IF UPDATE (column_name) ...*/
6

```

Figure 6-12. Trigger editor with default template

In the trigger editor, you can see that the template automatically names a new trigger Trigger1 prefixed with the name of the table. Actually, if another trigger with this name already exists, the new trigger is named Trigger2, and so on.

Once you are done editing your trigger, you need to save it by pressing Ctrl+S. As soon as you have saved it, the very first line of the stored procedure changes. The SQL statement CREATE TRIGGER is changed so that the first line reads as follows:

```
ALTER TRIGGER dbo. . . .
```

**NOTE** *The trigger editor performs syntax checking when you save your trigger, meaning if the syntax of your trigger is invalid, you aren't allowed to save it to your database.*

## EXERCISE

- 1) Create a new trigger for the tblUser table and save it with the name **tblUser\_Update**.
- 2) This is an update trigger, so you need to change the text on Line 3 to **FOR UPDATE**.
- 3) Replace the text on Line 5 and down with the following:

```
DECLARE @strFirstName varchar(50)
/* Get the value for the FirstName column */
SELECT @strFirstName = (SELECT FirstName FROM inserted)
/* Check if we're updating the LastName column.
If so, make sure FirstName is not NULL */
IF UPDATE (LastName) AND @strFirstName IS NULL
BEGIN
    /* Roll back update and raise exception */
    ROLLBACK TRANSACTION
    RAISERROR ('You must fill in both LastName and FirstName', 11, 1)
END
```

Now the stored procedure should look like the one in Figure 6-13.

```

1 ALTER TRIGGER tblUser_Update
2 ON dbo.tblUser
3 FOR UPDATE
4 AS
5     DECLARE @strFirstName varchar(50)
6     /* Get the value for the FirstName column */
7     SELECT @strFirstName = (SELECT FirstName FROM inserted)
8     /* Check if we're updating the LastName column.
9     If so, make sure FirstName is not NULL */
10    IF UPDATE (LastName) AND @strFirstName IS NULL
11    BEGIN
12        /* Roll back update and raise exception */
13        ROLLBACK TRANSACTION
14        RAISERROR ('You must supply both LastName and FirstName', 11, 1)
15    END
16

```

Figure 6-13. The tblUser\_Update trigger

4) Don't forget to save the changes using Ctrl+S.

When a trigger has been saved to the database, you can locate it under the table to which it belongs in the **Server Explorer**.

The tblUser\_Update trigger is invoked when updating a row in the user table. The trigger first tests to see if the LastName column is updated. If it is, then the trigger checks to see if the FirstName column is empty, because if it is the update is rolled back and an exception is raised. Please note that this trigger is designed to work with only one updated or inserted row at a time. If more rows are inserted at the same time, the trigger will have to be redesigned to accommodate this. However, this trigger only serves as a demonstration. The functionality of this trigger can easily be implemented using constraints, because the check I perform is done in the same table. If I had looked up a value in a different table, then the trigger would be your only choice.

Please see your SQL Server documentation if you need more information on how to create triggers. Listing 6-14 shows you how to execute the new trigger, demonstrating how to raise an exception you can catch in code.

*Listing 6-14. Invoking Trigger and Catching Exception Raised*

```

1 public void TestUpdateTrigger() {
2     const string STR_SQL_USER_SELECT = "SELECT * FROM tblUser";
3     const string STR_SQL_USER_DELETE = "DELETE FROM tblUser WHERE Id=@Id";
4     const string STR_SQL_USER_INSERT = "INSERT INTO tblUser(FirstName, " +
5         "LastName, LoginName) VALUES(@FirstName, @LastName, @LoginName)";
6     const string STR_SQL_USER_UPDATE = "UPDATE tblUser SET " +
7         " FirstName=@FirstName, LastName=@LastName, LoginName=@LoginName WHERE " +
8         " Id=@Id";
9
10    SqlConnection cnnUserMan;
11    SqlCommand cmmUser;
12    SqlDataAdapter dadUser;
13    DataSet dstUser;
14
15    SqlCommand cmmUserSelect;
16    SqlCommand cmmUserDelete;
17    SqlCommand cmmUserInsert;
18    SqlCommand cmmUserUpdate;
19
20    SqlParameter prmSQLDelete, prmSQLUpdate, prmSQLInsert;
21
22    // Instantiate and open the connection
23    cnnUserMan = new SqlConnection(STR_CONNECTION_STRING);
24    cnnUserMan.Open();
25
26    // Instantiate and initialize command
27    cmmUser = new SqlCommand("SELECT * FROM tblUser", cnnUserMan);
28    // Instantiate the commands
29    cmmUserSelect = new SqlCommand(STR_SQL_USER_SELECT, cnnUserMan);
30    cmmUserDelete = new SqlCommand(STR_SQL_USER_DELETE, cnnUserMan);
31    cmmUserInsert = new SqlCommand(STR_SQL_USER_INSERT, cnnUserMan);
32    cmmUserUpdate = new SqlCommand(STR_SQL_USER_UPDATE, cnnUserMan);
33    // Instantiate command and data set
34    cmmUser = new SqlCommand(STR_SQL_USER_SELECT, cnnUserMan);
35    dstUser = new DataSet();
36
37    dadUser = new SqlDataAdapter();
38    dadUser.SelectCommand = cmmUserSelect;
39    dadUser.InsertCommand = cmmUserInsert;
40    dadUser.DeleteCommand = cmmUserDelete;
41    dadUser.UpdateCommand = cmmUserUpdate;
42

```

```

43 // Add parameters
44 prmSQLDelete = dadUser.DeleteCommand.Parameters.Add("@Id", SqlDbType.Int,
45     0, "Id");
46 prmSQLDelete.Direction = ParameterDirection.Input;
47 prmSQLDelete.SourceVersion = DataRowVersion.Original;
48
49 cmmUserUpdate.Parameters.Add("@FirstName", SqlDbType.VarChar, 50,
50     "FirstName");
51 cmmUserUpdate.Parameters.Add("@LastName", SqlDbType.VarChar, 50,
52     "LastName");
53 cmmUserUpdate.Parameters.Add("@LoginName", SqlDbType.VarChar, 50,
54     "LoginName");
55 prmSQLUpdate = dadUser.UpdateCommand.Parameters.Add("@Id", SqlDbType.Int,
56     0, "Id");
57 prmSQLUpdate.Direction = ParameterDirection.Input;
58 prmSQLUpdate.SourceVersion = DataRowVersion.Original;
59
60 cmmUserInsert.Parameters.Add("@FirstName", SqlDbType.VarChar, 50,
61     "FirstName");
62 cmmUserInsert.Parameters.Add("@LastName", SqlDbType.VarChar, 50,
63     "LastName");
64 cmmUserInsert.Parameters.Add("@LoginName", SqlDbType.VarChar, 50,
65     "LoginName");
66
67 // Populate the data set from the view
68 dadUser.Fill(dstUser, "tblUser");
69
70 // Change the name of user in the second row
71 dstUser.Tables["tblUser"].Rows[1]["LastName"] = "Thomsen";
72 dstUser.Tables["tblUser"].Rows[1]["FirstName"] = null;
73
74 try {
75     // Propagate changes back to the data source
76     dadUser.Update(dstUser, "tblUser");
77 }
78 catch (Exception objE) {
79     MessageBox.Show(objE.Message);
80 }
81 }

```

In Listing 6-14, the second row is updated, and the LastName column is set to “Thomsen” and the FirstName to a **null** value. This will invoke the update trigger that throws an exception, which is caught in code and displays the error message.

This should give you a taste for using triggers, and they really aren't that hard to work with. Just make sure you have a well-designed database that doesn't use triggers for purposes that can easily be achieved by other means such as referential integrity.

## Viewing Trigger Source

In SQL Server Enterprise Manager, you can see the source for your triggers. Open up Enterprise Manager, expand your SQL Server, and expand databases and your database. Next, select the Tables node, right-click the table you have created the trigger for, and select All Task Manage Triggers from the pop-up menu. This brings up the Triggers Properties dialog box, where you can see and edit the triggers for the selected table.

In the Server Explorer in the VS .NET IDE, you can also view the trigger source by expanding your database, expanding the Tables node, expanding the table with the trigger, and double-clicking the trigger.

## Summary

In this chapter, I discussed how to create various server-side objects for server-side processing of your data. I demonstrated stored procedures, views, and triggers, and showed you how to create, run, and execute a stored procedure from code; how to create, run, and use a view from code, including updating the view; and finally how to create triggers.

I went into enough details about stored procedures, views, and triggers as to what a C# programmer needs to know, but if you are also responsible for coding the SQL Server database and you need more information and example code, I can certainly recommend you read this book:

- *Code Centric: T-SQL Programming with Stored Procedures and Triggers*, by Garth Wells. Published by Apress, February 2001. ISBN: 1893115836.

The next chapter is about hierarchical databases. I'll discuss how you use the LDAP protocol to access a network directory database like the Active Directory and you'll see how to access information stored on Exchange Server 2000.

- ADSID column in tblUser column for CUser class, details of, 514
- adsPath, retrieving from Active Directory with OLE DB .NET data providers, 432
- AFTER triggers, functionality of, 406
- aggregated data, using views for, 398
- Alias grid pane column in Query Designer, 326
- AllowDBNull DataColumn** class property, description of, 250
- AllowDelete DataView** class property, description of, 239
- AllowEdit DataView** class property, description of, 239
- AllowNew DataView** class property, description of, 239
- Alt+F11 keyboard shortcut, accessing Macros IDE with, 22
- anomalies in normal forms, explanation of, 46
- Antechinus C# Programming Editor, Web site for, 15
- Append grid pane column in Query Designer, 326
- Application Name **ConnectionString** property value, details of, 66–67
- ApplicationException** class, explanation of, 356
- ApplyDefaultSort DataView** class property, description of, 239
- Apress Web site
  - accessing, 57
  - downloading UserMan classes from, 567
- ArgumentException** exception, 351
  - handling for DataReader, 160
  - throwing, 113
  - thrown by **CommandTimeout** property, 143
  - thrown by **CommandType** property, 144
  - thrown by **UpdatedRowSource** property, 145–146
- ArgumentNullException** exception, 351, 353
- ArgumentOutOfRangeException** exception, 170, 351, 354
- arguments
  - advisory about usage with **SqlXmlAdapter** and **SqlXmlCommand** classes, 617
  - creating stored procedures with, 382–384
  - using stored procedures with, 384–385
- arguments and return values, running stored procedures with, 385–387
- ASP (Active Server Pages), evolution of, 5
- ASP.NET data binding, maintaining state in, 548–549
- ASP.NET, explanation of, 5
- ASP.NET server controls, binding to data sources, 545–548
- assemblies
  - functionality of, 9–11
  - interaction of namespaces with, 13
- assembly attributes, customizing, 11
- Assert Debug** class method, 363
- assertions
  - definition of, 360
  - using with **Debug** class, 362–364
- asterisks (\*), advisory about, 434
- AttachDBFilename **ConnectionString** property value, details of, 66–67
- AttributeCount XmlReader** class property, 162
- auditing, securing message queuing with, 502
- authenticated messages, sending, 494–495
- authentication, securing message queuing with, 490–495

- AuthenticationType** property of **DirectoryEntry** class, description of, 417
- AUTO SELECT . . . FOR XML statement keyword, description of, 588
- AutoIncrement DataColumn** class property, description of, 250
- AutoIncrementSeed DataColumn** class property, description of, 250
- AutoIncrementStep DataColumn** class property, description of, 250
- automatic garbage collection, role in .NET Framework, 8
- automatic transactions
  - explanation of, 110
  - use of, 586
- B**
- backslash (\) in Active Directory hierarchies, 420
- BaseUri XmlReader** class property, 162
- BEFORE triggers, functionality of, 406
- Begin** method of **Transaction** class, description of, 109
- BeginEdit DataRow** class property, description of, 246
- BeginLoadData DataTable** class method, description of, 221
- BeginTransaction** method
  - exception handling, 111–112
  - of **OdbcConnection** class, 83, 101
  - of **OleDbConnection** class, 81
  - of **SqlConnection** class, 80, 100–101
- BINARY BASE64 SELECT . . . FOR XML statement keyword, description of, 588
- binding context, examining for Windows forms, 527–528
- BindingContext** object, role in Windows forms, 527–528, 538–539
- Bindings** property of **CurrencyManager** class, description of, 540
- Body setting for message queue encryption, explanation of, 497–498
- BOF (Beginning-Of-File), moving cursors to, 263–264
- Broken** member of **ConnectionState** Enum, description of, 89
- broken ownership chain, explanation of, 376
- browsers
  - appearance after restarting virtual directory in SQLXML 2.0, 602
  - troubleshooting in SQLXML 2.0, 609–610
- browsing scope, definition of, 19
- Bulk Load feature of SQLXML 2.0, resource for, 593
- C**
- \*.cmd extension, explanation of, 303
- C (country) moniker, role in LDAP syntax, 421
- C# keywords related to OOP, list of, 510–511
- Cancel** Command class method, description of, 138
- CancelCurrentEdit CurrencyManager** class method, description of, 540
- CancelEdit DataRow** class property, description of, 246
- CanResolveEntity XmlReader** class property, 162
- Caption DataColumn** class property, description of, 250
- cascades, role in referential integrity, 44
- CaseSensitive** property
  - of **DataSet** class, 197
  - of **DataTable** class, 219
- catch** blocks
  - role in exception handling, 344, 348–349
  - role in filtering exceptions, 355
- ChangeDatabase** method
  - of **OleDbConnection** class, 81, 83
  - of **SqlConnection** class, 80
  - throws exception, 114
- Chaos** member of **IsolationLevel** Enum, description of, 102
- child tables
  - explanation of, 39
  - and referential integrity, 44–45
- ChildColumns DataRelation** class property, description of, 254
- ChildKeyConstraint DataRelation** class property, description of, 254
- ChildRelations DataTable** class property, description of, 219
- Children** property of **DirectoryEntry** class, description of, 417
- ChildTable DataRelation** class property, description of, 254
- Class View in Solution Explorer, switching to, 507
- classes, wrapping as components, 582
- clear **DataSet**, explanation of, 209
- clear **DataTable**, explanation of, 227
- Clear** method
  - of **DataSet** class, 199
  - of **DataTable** class, 221

- ClearErrors DataRow** class property, description of, 246
- client-side cursors, explanation of, 262
- clients, creating for UserMan example application, 582–583
- close connection, explanation of, 86
- Clone** method
  - of **DataSet** class, 199
  - of **DataTable** class, 221
  - using with **DataSet** objects, 210
  - using with **DataTable** objects, 228
- Close** method
  - of **DataReader** class, 152
  - of **DirectoryEntry** class, 419
  - of **OdbcConnection** class, 83
  - of **OleDbConnection** class, 81
  - of **SqlConnection** class, 80
  - of **XmlReader** class, 164
- Closed** member of **ConnectionState** Enum, description of, 89
- CLR (common language runtime)
  - handling exceptions with, 359
  - versus JVM, 9
  - .NET Framework adherence to, 6–8
- CLR tasks, built-in type of, 7
- CLS (Common Language Specification), .NET Framework adherence to, 4, 6
- CN (common name) moniker, role in LDAP syntax, 420–421
- code, running simple stored procedures from, 380–382, 401–405
- column and row change events, examining order of, 232–233
- column attributes for tables, displaying with Database Designer, 310
- column changes, handling in **DataTable** objects, 233–234
- Column grid pane item in Query Designer, 326
- ColumnChanged DataTable** class event, description of, 224
- ColumnChanging DataTable** class event, description of, 224
- ColumnMapping DataColumn** class property, description of, 250
- ColumnName DataColumn** class property, description of, 250
- columns
  - adding to tables with Table Designer, 315–316
  - checking for null values in, 149–150
  - choosing in Data Form Wizard, 532
  - in database table rows, definition of, 36
  - role in databases, 36
  - sorting with Query Designer, 324
- Columns DataTable** class property, description of, 219
- COM components, using from within .NET Framework, 276–278
- COM Interop
  - resource for, 56
  - using with ADO.NET disconnected layer, 276–278
- COM types, generating metadata for, 277–278
- Command class
  - methods, 129–137
  - properties, 138–139
- command files, adding for scripts, 303–304
- command mode, role in VS .NET IDE, 18–19
- command object parameters, adding to UserMan example application, 575–576
- Command objects
  - instantiating for UserMan database, 573–574
  - using in ADO.NET connected layer, 123
- command properties, setting in ADO.NET connected layer, 178–184
- Command Window in VS .NET IDE, modes for, 18–19
- CommandBuilder class, using in ADO.NET connection layer, 188–191
- commands, executing in ADO.NET connected layer, 139–142
- CommandText** property
  - of **OdbcCommand** class, 135
  - of **OleDbCommand** class, 132
  - of **SqlCommand** class, 130
- CommandTimeout** property
  - of **OdbcCommand** class, 135of
  - OleDbCommand** class, 132
  - of **SqlCommand** class, 130
  - throws **ArgumentException** exception, 143
- CommandType** property
  - of **OdbcCommand** class, 135–136
  - of **OleDbCommand** class, 132–133
  - of **SqlCommand** class, 130
  - throws **ArgumentException** exception, 144
- Commit** method of Transaction class, description of, 109
- CommitChanges DirectoryEntry** class method, description of, 419

- Committed** member of **MessageQueueTransactionStatus** Enum, description of, 483
- common language runtime. *See* CLR
- Common Language Specification. *See* CLS
- common type system. *See* CTS
- compare connections, explanation of, 87–88
- comparisons, performing in ADO.NET connected layer, 87
- components, wrapping classes as, 582
- composite keys
  - in databases, definition of, 43
  - role in databases, 43
- Computer Management MMC versus Server Explorer, advisory when creating public message queues, 457
- Compute** **DataTable** class method, description of, 221
- concurrency violations
  - handling, 273–275
  - ignoring, 271–273
  - occurrence of, 269–270
- Connect As dialog box, displaying, 287
- Connect Timeout or Connection Timeout **ConnectionString** property value, details of, 68–69
- Connecting** member of **ConnectionState** Enum, description of, 89
- Connection class
  - events, 84–85
  - exceptions handling, 110–123
  - explanation of, 63
  - functionality of, 63–64
  - methods of, 80–84
  - properties of, 76–79
- Connection Lifetime **ConnectionString** property value, details of, 68–69
- Connection objects, comparing in ADO.NET connected layer, 87–88
- Connection OdbcCommand** class property, details of, 136
- Connection OleDbCommand** class property, details of, 133
- connection oriented programming, explanation of, 450
- connection pools
  - explanation of, 90–96
  - resetting connections in, 93
- Connection** property of Transaction class, description of, 108
- Connection Reset **ConnectionString** property value, details of, 70–71
- Connection Reset value, resetting connections in connection pools with, 93
- Connection SqlCommand** class property, details of, 130
- connection state, manipulating in ADO.NET connected layer, 88–96
- connection state messages, handling in ADO.NET connected layer, 97–98
- connectionless programming, explanation of, 450
- connections
  - choosing in Data Form Wizard, 530
  - closing in ADO.NET connection layer, 86
  - deleting with Server Explorer, 285
  - disposing in ADO.NET connected layer, 86–87
  - handling with Server Explorer, 282–285
  - opening in ADO.NET connected layer, 85–86
  - removing from pools, 92
  - setting with VS .NET IDE, 26
- ConnectionState**, comparing **State** to, 89
- ConnectionString** property
  - examining after setting, 76
  - example of white space in, 91
  - exception handling, 112–113
  - functionality of, 65
  - values for, 66–75
- ConnectionTimeout** property
  - exception handling, 113
  - of **OdbcConnection** class, 79
  - of **OleDbConnection** class, 78
  - of **SqlConnection** class, 77
- constraints, adding with Table Designer, 319–320
- Constraints DataTable** class property, description of, 219
- constructors, adding to CUser class for wrapped databases, 518–519
- Contains** public property and method of **BindingContext** class, description of, 538
- ContinueUpdateOnError** DataAdapter class property, description of, 172

- copy **DataSet**, explanation of, 209
  - copy **DataSet** structure, explanation of, 210
  - copy **DataTable**, explanation of, 227
  - copy **DataTable** rows, explanation of, 230–232
  - copy **DataTable** structure, explanation of, 227
  - Copy** method
    - of **DataSet** class, 200
    - of **DataTable** class, 222
  - CopyTo DataView** class method, 240
  - CopyTo DirectoryEntry** class method, description of, 419
  - Count DataView** class property, description of, 239
  - Count** property of **CurrencyManager** class, description of, 540
  - Create Command File dialog box, displaying, 303
  - Create Database dialog box, displaying, 292
  - Create Message Queue dialog box, displaying, 290
  - CreateCommand** method
    - of **OdbcConnection** class, 83
    - of **OleDbConnection** class, 81
    - of **SqlConnection** class, 80
  - CreateParameter** Command class method, description of, 138
  - Criteria grid pane column in Query Designer, 326
  - cross-language inheritance, role in .NET Framework, 8
  - Ctrl+Alt+J keyboard shortcut, opening Object Browser with, 19
  - Ctrl+Alt+K keyboard shortcut, accessing Task List window with, 27
  - Ctrl+Alt+S keyboard shortcut, accessing Server Explorer with, 281
  - Ctrl+S keyboard shortcut
    - saving changes to stored procedures with, 381, 383
    - saving database diagrams with, 310
    - saving SQL Editor scripts with, 336
    - saving triggers with, 408
    - saving views with, 399
  - Ctrl+Shift+C keyboard shortcut, switching to Class View in Solution Explorer with, 507
  - Ctrl+Shift+N keyboard shortcut, displaying New Project dialog box with, 296
  - CTS (common type system), .NET Framework adherence to, 4, 6
  - Culture, Processor, OS, manifest components of assemblies, description of, 10
  - CurrencyManager** class methods and properties, 540–541
  - CurrencyManager** object, role in Windows forms, 527, 538–544
  - Current Language **ConnectionString** property value, details of, 70–71
  - Current** property of **CurrencyManager** class, description of, 540
  - cursor locations, options for, 262–263
  - cursor types, 263–265
  - cursors, using in ADO.NET disconnected layer, 261–265
  - CUser class
    - adding command object parameters to, 575–576
    - adding constructors and destructors to, 518–519
    - adding error event class to, 520–521
    - adding events to, 519–524
    - creating, 513–524
    - declaring event and method raising event for, 522
    - declaring event delegate for, 522
    - displaying method receiving event in, 523
    - displaying private database constants and variables for, 567–568
    - filling data sets in, 576
    - hooking event receiver with event in, 523
    - hooking up public properties to data sets in, 576–578
    - instantiating and initializing data adapters in, 574–575
    - instantiating command objects in, 573–574
    - instantiating **DataSet** objects in, 574
    - locating code for, 579
    - making connection object shared in, 570
    - opening database connection for, 570–572
    - setting maximum column length variables for, 569–570
    - specifying parent classes in, 578
    - triggering invalid LoginName error event in, 523
- ## D
- DAP (Directory Access Protocol), introduction to, 413

- data
  - displaying in databases, 397
  - manipulating in views from code, 402–405
- data adapters, instantiating and initializing in UserMan example application, 574–575
- data binding, suspending and resuming, 543–544
- data-bound controls
  - choosing right data storage for, 549–551
  - communication with data sources, 528
  - controlling validation of edit operations in, 543–544
  - versus manual data hooking, 525–526
  - retrieving current row of data sources for, 542
  - retrieving and setting current position in data sources for, 542–543
  - retrieving number of rows in data sources for, 542
  - using Data Form Wizard with, 528–536
  - using with Web forms, 545–551
  - using with Windows forms, 527
- data-bound Web forms, creating and updating, 551–561
- data-bound Windows form controls, creating, 544
- data classes for .NET Data Providers, list of, 63
- data connections
  - choosing in Data Form Wizard, 530
  - closing in ADO.NET connection layer, 86
  - deleting with Server Explorer, 285
  - disposing in ADO.NET connected layer, 86–87
  - handling with Server Explorer, 282–285
  - opening in ADO.NET connected layer, 85–86
  - removing from pools, 92
  - setting with VS .NET IDE, 26
- data distribution, performance resources optimization of, 369
- Data Form Wizard
  - choosing data connections in, 530
  - choosing data display in, 533
  - choosing data sets in, 529
  - choosing tables and columns in, 532
  - choosing tables and views in, 531
  - creating data-binding forms with, 551–557
  - creating forms for data-bound controls with, 528–536
  - examining code created by, 536–537
  - examining frmUser.cs file in, 537
  - examining objUser object declaration in, 536–537
  - opening frmUser form with, 536
  - role of **Dispose** methods in, 536
  - sample form created by, 534
- data integrity
  - in databases, explanation of, 44
  - role in databases, 44
- Data Link Properties dialog box, displaying, 283–284
- data providers
  - in ADO.NET connected layer, 59–62
  - role in ADO and ADO.NET, 57
- data-related exceptions, handling, 357–359
- data-related namespaces, role in ADO.NET connected layer, 58–59. *See also* namespaces
- data sets
  - choosing in Data Form Wizard, 529
  - filling in UserMan example application, 576
- Data Source **ConnectionString** property value, details of, 66–67
- data source locking, role in ADO.NET disconnected layer, 265–276
- data source messages, handling in ADO.NET connection layer, 97–98
- data sources
  - binding ASP.NET server controls to, 545–548
  - binding Windows form controls to, 537–538
  - locking data at, 266–268
  - retrieving and setting current position for data-bound controls, 542–543
  - retrieving number of rows for data-bound controls, 541–542
  - updating from **DataSet** objects, 618–619
  - updating with DataAdapter classes, 206–209
  - updating with **SqlXmlCommand** class, 631–635
- data storage, choosing for data-bound controls, 549–551
- data wrappers
  - definition of, 505

- reasons for use of, 505
- DataAdapter classes
  - explanation of, 170–171
  - events, 174–175
  - methods of, 173–174
  - populating **DataSet** objects with, 203–206
  - preparing for **CommandBuilder** class, 189–191
  - properties of, 172
  - role in ADO.NET, 59, 170–172
  - setting command properties, 178–184
  - updating data sources with, 206–209
- DataAdapter object, instantiating, explanation of 176–178
- Database **ConnectionString** property
  - value, details of, 66–67
- DATABASE **ConnectionString** property
  - value, details of, 66–67
- Database Designer
  - adding relationships with, 311
  - adding tables with, 309
  - creating tables with, 309–313
  - deleting and removing tables with, 309
  - deleting relationships with, 311
  - designing databases with, 306–313
  - displaying column attributes with, 310
  - editing database properties with, 311
- database diagrams
  - changing table views for, 313
  - changing viewable area of, 312
  - creating with Database Designer, 306–313
  - moving view ports in, 312–313
  - overview of, 311–312
  - saving, 314
  - showing relationship names in, 312
  - sizing tables automatically in, 313
  - zooming in, 311–312
- database objects
  - adding to database projects, 300–304
  - creating with Server Explorer, 285
  - identifying, 37
- database projects
  - adding database objects to, 300–304
  - creating, 296–298
  - creating folders for, 298–299
  - definition of, 296
  - deleting folders from, 299
- database properties, editing with Database Designer, 311
- Database property
  - of **OdbcConnection** class, 79
  - of **OleDbConnection** class, 78
  - of **SqlConnection** class, 77
  - throws exceptions, 114
- Database Query database object template, description of, 301
- database tables versus message queues, 452
- databases. *See also* SQL Server databases
  - benefits of, 32–33
  - columns in, 36
  - composite keys in, 43
  - data integrity in, 44
  - declarative referential integrity (DRI) in, 45
  - definition of, 31–32
  - designing with Database Designer, 306–313
  - designing with Visio for Enterprise Architect, 305
  - determining objects for, 37–38
  - displaying data in, 397
  - domain integrity in, 45
  - entity integrity in, 44
  - fields in, 36
  - foreign keys in, 42–43
  - hierarchical, description of, 33–34
  - indexes in, 43
  - keys in, 42
  - lookup keys in, 42
  - normalization in, 46
  - null values in, 36
  - primary keys in, 42–43
  - procedural referential integrity (PRI) in, 45
  - reasons for use of, 32–33
  - records in, 36
  - referential integrity in, 44–45
  - rows in, 36
  - tables in, 36
  - wrapping, 513–524
- DataBind** method, role in binding ASP.NET server controls to data sources, 545, 547–548
- DataBindings dialog box, displaying, 560
- DataColumn** class
  - properties of, 250–252
  - using in ADO.NET disconnected layer, 249–252
- DataColumn** objects, declaring and instantiating, 252
- DataGrid Properties dialog box, displaying, 553
- DataGridCancelCommand** event procedure, displaying, 554–555
- DataGridEditCommand** event procedure, displaying, 553

- DataGridUpdateCommand** event procedure, displaying, 555–556
- DataReader** classes
  - closing, 149
  - exception handling, 160
  - handling multiple results with, 150
  - instantiating, 176–178
  - methods of, 151–160
  - properties of, 151
  - reading rows in, 148
  - usage of, 160–161
  - use of server-side cursors by, 263
  - using with ADO.NET connected layer, 146
- DataReader** objects, declaring and instantiating, 147–148
- DataRelation** class
  - properties of, 254
  - using in ADO.NET disconnected layer, 252–261
- DataRelation** objects
  - declaring and instantiating, 254–256
  - exceptions, 253
- DataRow** and **DataColumn** classes, functionality of, 232–233
- DataRow** class, using in ADO.NET disconnected layer, 245–249
- DataRow** objects
  - building, 249
  - declaring and instantiating, 249
- DataSet** class
  - events of, 202–203
  - methods of, 199–201
  - properties of, 197–199
  - using with ADO.NET disconnected layer, 193–194
- DataSet Designer**, creating typed data sets with, 338–340
- DataSet** objects
  - accepting or rejecting changes to data in, 214–218
  - building UserMan database schema as, 256–261
  - clearing data from, 209
  - copying data and structures of, 209–210
  - detecting and handling changes to data in, 212–214
  - instantiating, 203
  - instantiating in CUser class, 574
  - merging data between, 210–212
  - populating with DataAdapter class, 203–206
  - populating with **SqlXmlAdapter** class, 614–616
  - updating data sources from, 618–619
  - using **AcceptChanges** method with, 215
  - using **RejectChanges** method with, 216–218
  - using with data-bound controls, 550
- DataSet** property
  - of **DataRelation** class, 254
  - of **DataTable** class, 219
- DataSetName DataSet** class property, description of, 197
- DataSource** property
  - of **OdbcConnection** class, 79
  - of **OleDbConnection** class, 78
  - of **SqlConnection** class, 77
- DataTable** class
  - events of, 223–224
  - methods of, 220–223
  - properties of, 218–220
  - using with **DataSet** class, 194, 218–223
- DataTable** objects
  - building, 225–227
  - clearing data from, 227
  - copying, 227–229
  - copying rows in, 230–232
  - declaring and instantiating, 224–225
  - examining order of column and row change events in, 232–233
  - handling column changes in, 233–234
  - handling row changes in, 235–236
  - handling row deletions in, 236–238
  - merging **DataSet** objects with, 212
  - populating, 227
  - searching and retrieving filtered data views from, 229–230
  - using with CommandBuilder class, 188–189
- DataType DataColumn** class property, description of, 250
- DataView** class
  - events of, 241
  - methods of, 240
  - properties of, 239
  - using in ADO.NET disconnected layer, 238–245
- DataView** objects
  - declaring and instantiating, 242
  - searching, 243
  - sorting, 244–245
- DataViewManager DataView** class
  - property, description of, 239
- DBCC** (Database Consistency Checker), functionality of, 371–372
- DBMS** (database management system), definition of, 35

- dbo (database owner), role in creating SQL Server stored procedures, 376
  - DBObject virtual name, querying objects with, 605–606
  - DBQ **ConnectionString** property value, details of, 66–67
  - DC (domain component) moniker, role in LDAP syntax, 421
  - dead-letter message queues
    - explanation of, 485–486
    - rejecting messages in, 492
  - debug assertions, using, 363–364
  - Debug** class
    - advisory about, 364
    - methods and properties of, 366
    - using, 359–366
    - using error messages with, 364–366
  - debugger in VS .NET IDE, explanation of, 20–21
  - debugging, enabling and disabling, 360–362
  - DefaultValue DataColumn** class property, description of, 250
  - DefaultView DataTable** class property, description of, 219
  - DefaultViewManager DataSet** class property, description of, 197
  - Delete DataRow** class property, description of, 246
  - Delete DataView** class method, 240
  - DELETE queries, using Query Designer for, 331–332
  - DeleteCommand** DataAdapter class property, description of, 172
  - DeleteTree DirectoryEntry** class method, description of, 419
  - denormalization, explanation of, 51
  - deployment tools, upgrades in VS .NET IDE, 23
  - Depth** property of DataReader class, description of, 151
  - Depth XmlReader** class property, 162
  - DesignTimeVisible** property
    - of **OdbcCommand** class, 136
    - of **OleDbCommand** class, 133
    - of **SqlCommand** class, 130
  - destructors, adding to CUser class for wrapped databases, 518–519
  - deterministic finalization versus automatic garbage collection, 8
  - diagram pane of Query Designer, functionality of, 322–325
  - DiffGrams
    - advisory about using with SQLXML 2.0 Managed classes, 619
    - generating and executing, 633–635
  - direct URL queries in SQLXML 2.0, advisory about, 606
  - DirectoryEntries** class in **System.DirectoryServices** namespace, description of, 416
  - DirectoryEntry** class
    - description of, 416
    - methods of, 419–420
    - studying in Active Directory, 417–422
    - in **System.DirectoryServices** namespace, 415
  - DirectorySearcher** class
    - description of, 416
    - in **System.DirectoryServices** namespace, 415
    - using with objects in Active Directory, 422–423
  - DisplayExpression DataTable** class property, description of, 219
  - Dispose** methods, role in Data Form Wizard code, 536
  - dispose of connection, explanation of, 86–87
  - distributed applications versus stand-alone applications, 368
  - DLL (dynamic link library) classes versus assemblies, 10
  - DN (distinguished name), role in Active Directory, 420
  - domain integrity in databases, explanation of, 45
  - DRI (declarative referential integrity) in databases, explanation of, 45
  - DRIVER ConnectionString** property value, details of, 66–67
  - driver messages, handling in ADO.NET connection layer, 97–98
  - Driver OdbcConnection** class property, description of, 79
  - drivers. *See* OLE DB drivers
  - DSN **ConnectionString** property value, details of, 68–69
  - dynamic cursors, explanation of, 265
  - Dynamic Help, role in VS .NET IDE, 21–22
- ## E
- edit mode, generating data-bound Web forms in, 555
  - edit operations, controlling validation for data-bound controls, 543–544
  - ELEMENTS SELECT . . . FOR XML statement keyword, description of, 588

- encapsulation, role in OOP, 510
  - encrypted messages, sending and receiving, 498–499
  - encryption
    - securing message queuing with, 495–499
    - using views for, 398
  - EndCurrentEdit CurrencyManager** class method, description of, 540
  - EndEdit DataRow** class property, description of, 246
  - EndLoadData DataTable** class method, description of, 222
  - EnforceConstraints DataSet** class property, description of, 197
  - Enlist **ConnectionString** property value, details of, 70–71
  - entity integrity
    - in databases, explanation of, 44
    - role in databases, 44
  - enums, tip when passing arguments to methods and properties, 522
  - EOF XmlReader** class property, 162
  - equal to (=) column comparison symbol, role in Query Designer join types, 323
  - Equals** method, using in ADO.NET connected layer, 87–88
  - Equals** method
    - of **OdbcConnection** class, 83
    - of **OleDbConnection** class, 82
    - of **SqlConnection** class, 80
  - ER/Studio, Web site for, 37
  - ErrorCode** property of **OleDbException** class, details of, 117
  - Errors** property
    - of **OdbcException** class, 121
    - of **OleDbException** class, 117
  - ERwin, Web site for, 37
  - events, adding to CUser class for wrapped databases, 519–524
  - Exception** class
    - examining, 346–348
    - methods of, 348
  - exception handlers
    - handling exceptions in, 348–354
    - using two or more in single procedures, 345–346
  - exception handling
    - enabling, 345
    - functionality of, 343–344
    - role of **catch** blocks in, 344
    - role of **finally** blocks in, 344–345
    - role of **try** statement in, 344
    - types of handlers in, 345
  - Exception** type, 350
  - exceptions
    - CLR handling of, 359
    - creating, 356
    - filtering, 354–356
    - handling data-related type of, 357–359
    - throwing, 356–357
    - types of, 350–351
    - understanding generation of, 111
  - Exchange Server 2000
    - accessing, 436–447
    - accessing as linked server from SQL Server, 442–447
    - retrieving contacts for UserMan user from, 438–439
    - reviewing content of sample folder with, 440–441
  - ExecuteNonQuery** method
    - description of, 138
    - usage of, 140–141, 631–632
  - ExecuteReader** method
    - description of, 138
    - usage of, 140–141
  - ExecuteScalar** method
    - description of, 138
    - usage of, 140, 142
  - ExecuteXmlReader** method
    - description of, 139
    - usage of, 140, 142
  - Executing** member of **ConnectionState** Enum, description of, 89
  - Exists DirectoryEntry** class method, description of, 419
  - ExOLEDB (Microsoft OLE DB Exchange Server Provider), using, 438–439
  - EXPLICIT SELECT . . . FOR XML statement keyword, description of, 588
  - Expression DataColumn** class property, description of, 251
  - ExtendedProperties** property
    - of **DataColumn** class, 251
    - of **DataRelation** class, 254
    - of **DataSet** class, 197
    - of **DataTable** class, 219
  - external transactions, role in message queues, 480
- ## F
- Fail** method, role in using error messages with Debug class, 365
  - FAQs (Frequently Asked Questions), about databases, list of, 35–51
  - fault handlers, role in exception handling, 345

- Fetching** member of **ConnectionState** Enum, description of, 89
  - FieldCount** property of **DataReader** class, description of, 151
  - fields, role in databases, 36
  - FIFO (First In, First Out) principle versus message queues, 453
  - FIL **ConnectionString** property value, details of, 70–71
  - file-based XML templates, executing from code with SQLXML 2.0, 617
  - File Name **ConnectionString** property value, details of, 70–71
  - File Table manifest component of assemblies, description of, 10
  - Fill** method
    - of **DataAdapter** class, 173
    - populating **DataSet** objects with, 203–206
  - fill operation errors, handling in ADO.NET connection layer, 184–185
  - FillError** **DataAdapter** class event, description of, 175
  - FillSchema** **DataAdapter** class method, description of, 173
  - filter handlers, role in exception handling, 345
  - finally** blocks, role in exception handling, 344–345
  - finally** handlers, role in exception handling, 345
  - Find DataView** class method, 240
  - FindRows DataView** class method, 240
  - FirstName column in tblUser column for CUser class, details of, 514
  - folders
    - creating for database projects, 298–299
    - deleting for database projects, 299
  - foreign keys
    - in databases, definition of, 42
    - role in databases, 42–43
  - ForeignKeyConstraint** objects, advisory when using **DataSet** objects, 215
  - format names, binding to existing message queues with, 460–461
  - formatters, using with message queues, 464–467
  - forms, creating for data binding, 551–557
  - forms for data-bound controls, creating with Data Form Wizard, 528–536
  - forward-only cursors, explanation of, 263–264
  - friendly names, binding to existing message queues with, 459–460
  - frmUser form, opening with Data Form Wizard, 536
  - frmUser.cs file, examining in Data Form Wizard, 537
- ## G
- garbage collection, role in .NET Framework, 7–8
  - Generate Dataset dialog box, displaying, 559
  - Get\*** methods of **DataReader** class, 152–159
  - GetAttribute XmlReader** class method, 164
  - GetBaseException** method
    - of **OdbcException** class, 123
    - of **OleDbException** class, 119
  - GetBoolean** method of **DataReader** class, 152
  - GetByte** method of **DataReader** class, 152
  - GetBytes** method of **DataReader** class, 152
  - GetChanges** method
    - of **DataSet** class, 200
    - of **DataTable** class, 222
  - GetChar** method of **DataReader** class, 153
  - GetChars** method of **DataReader** class, 153
  - GetChildRows DataRow** class property, description of, 247
  - GetColumnError DataRow** class property, description of, 247
  - GetColumnsInError DataRow** class property, description of, 247
  - GetDataTypeName** method of **DataReader** class, 153
  - GetDateTime** method of **DataReader** class, 153
  - GetDecimal** method of **DataReader** class, 153
  - GetDouble** method of **DataReader** class, 154
  - GetEnumerator DataView** class method, 240
  - GetErrors DataTable** class method, description of, 222
  - GetFieldType** method of **DataReader** class, 154
  - GetFillParameters** **DataAdapter** class method, description of, 174

- GetFloat** method of **DataReader** class, 154
  - GetGuid** method of **DataReader** class, 154
  - GetHashCode** method
    - of **OdbcConnection** class, 83
    - of **SqlConnection** class, 80
  - GetInt16** method of **DataReader** class, 154
  - GetInt32** method of **DataReader** class, 154
  - GetInt64** method of **DataReader** class, 155
  - GetName** method of **DataReader** class, 155
  - GetOleDbSchemaTable**
    - OleDbConnection** class
    - method, details of, 82
  - GetOrdinal** method of **DataReader** class, 155
  - GetParentRow DataRow** class property, description of, 247
  - GetParentRows DataRow** class property, description of, 248
  - GetSchemaTable** method of **DataReader** class, 155
  - GetSqlBinary** method of **DataReader** class, 155
  - GetSqlBoolean** method of **DataReader** class, 156
  - GetSqlByte** method of **DataReader** class, 156
  - GetSqlDateTime** method of **DataReader** class, 156
  - GetSqlDecimal** method of **DataReader** class, 156
  - GetSqlDouble** method of **DataReader** class, 156
  - GetSqlGuid** method of **DataReader** class, 156
  - GetSqlInt16** method of **DataReader** class, 157
  - GetSqlInt32** method of **DataReader** class, 157
  - GetSqlInt64** method of **DataReader** class, 157
  - GetSqlMoney** method of **DataReader** class, 157
  - GetSqlSingle** method of **DataReader** class, 157
  - GetSqlString** method of **DataReader** class, 157
  - GetSqlValue** method of **DataReader** class, 158
  - GetSqlValue** method of **DataReader** class, 158
  - GetSqlValues** method of **DataReader** class, 158
  - GetString** method of **DataReader** class, 158
  - GetTimeSpan** method of **DataReader** class, 158
  - GetType** method
    - of **OdbcConnection** class, 83
    - of **OleDbConnection** class, 82
    - of **SqlConnection** class, 80
  - GetValue** method of **DataReader** class, 158
  - GetValues** method of **DataReader** class, 159
  - GetXml DataSet** class method, description of, 200
  - GetXmlSchema DataSet** class method, description of, 200
  - greater than (>) column comparison symbol, role in Query Designer join types, 323
  - greater than or equal to (>=) column comparison symbol, role in Query Designer join types, 323
  - grid pane of Query Designer, functionality of, 325–327
  - Group By grid pane column in Query Designer, 326
  - guarded blocks of code, using exception handlers with, 345
  - Guid** property of **DirectoryEntry** class, description of, 417
- ## H
- Has . . . a inheritance, explanation of, 507
  - HasAttributes XmlReader** class property, 162
  - HasChanges DataSet** class method, description of, 200
  - HasErrors** property
    - of **DataRow** class, 245
    - of **DataSet** class, 198
    - of **DataTable** class, 219
  - HasValue XmlReader** class property, 162
  - HasVersion DataRow** class property, description of, 248
  - Help system, integration in VS .NET IDE, 21–22
  - HelpLink** property
    - of **Exception** class, 347
    - of **OdbcException** class, 121
    - of **OleDbException** class, 117
  - hierarchical databases, description of, 33–34

- hierarchical versus relational databases, 33–35
- HResult** property
  - of **OdbcException** class, 121
  - of **OleDbException** class, 118
- I**
- ICT Database Designer Tool, Web site
  - for, 37
- Id column in tblUser column for CUser class, details of, 514–515
- Identity manifest component of assemblies, description of, 10
- IDEs (Integrated Development Environments). *See also* VS .NET IDE
  - running scripts in, 302
  - running simple stored procedures from, 379–380
  - running stored procedures with arguments from, 384
  - running views from, 400–401
- IDL (Interface Definition Language) files, role in language compilation, 8
- IDs, retrieving for message queues, 458–459, 468–469
- immediate mode, role in VS .NET IDE, 18–19
- implementation inheritance, role in OOP, 509–510
- ImportRow** method, using with **DataTable** objects, 232
- ImportRow DataTable** class method, description of, 222
- IMS (Information Management System), Web site for, 34
- indexes
  - adding with Table Designer, 317–319
  - in databases, definition of, 43
  - role in databases, 43
- IndexOutOfRangeException** exception, 350, 352, 355
- InferXmlSchema DataSet** class method, description of, 200
- InfoMessage** Connection class event, details of, 85
- information hiding, role in OOP, 510
- inheritance, role in OOP, 507–510
- Initial Catalog **ConnectionString** property value, details of, 70–71
- Initial File Name **ConnectionString** property value, details of, 70–71
- Initialized** member of **MessageQueueTransactionStatus** Enum, description of, 483
- InnerException** property
  - of **Exception** class, 347
  - of **OdbcException** class, 122
  - of **OleDbException** class, 118
- INSERT queries, using Query Designer
  - for, 333
- INSERT triggers, functionality of, 406
- InsertCommand** DataAdapter class
  - property, description of, 172
- integrated debugger in VS .NET IDE, explanation of, 20–21
- Integrated Security **ConnectionString** property value, details of, 70–71
- interface inheritance, role in OOP, 507–509
- interface** keyword in C#, relationship to OOP, 511
- interface modes for VS .NET IDE, explanation of, 16
- interfaces, creating and implementing with OOP, 508–509
- internal transactions, role in message queues, 480–481
- Interop Assemblies, location of, 278
- InvalidCastException** exception
  - handling for **DataReader** class, 160
  - thrown by **XmlReader** methods, 164
- InvalidConstraintException** exception
  - thrown by **DataRelation** class, 253
- InvalidOperationException** exception, 351–352
  - handling for **DataReader** class, 160
  - handling for **XmlReader** class, 170
  - throwing, 111–112, 115, 144–145
- Invoke DirectoryEntry** class method, description of, 419
- Is a . . . inheritance, explanation of, 507, 509
- ISAPI extension
  - configuring for SQLXML 2.0, 593–598
  - testing for SQLXML 2.0, 599
- IsClosed** property of **DataReader** class, description of, 151
- IsDBNull** method of **DataReader** class, 159
- IsDefault XmlReader** class property, 162
- IsEmptyElement XmlReader** class
  - property, 162
- IsName XmlReader** class method, 164
- IsNameToken XmlReader** class method, 164
- IsNull DataRow** class property, description of, 248

isolation levels, determining for running transactions, 107–108

**IsolationLevel** Enum, members of, 102

**IsolationLevel** property of Transaction class, description of, 108

**IsReadOnly** public property and method of **BindingContext** class, description of, 538

**IsStartElement XmlReader** class method, 164

**ItemArray DataRow** class property, description of, 245

## J

JIT (Just in Time) compiler, functionality of, 9

join dependence, role in 5NF, 51

join types, changing with diagram pane of Query Designer, 323–324

journal storage

controlling size of, 489–490

retrieving messages from, 489

using with message queues, 486–490

JScript, implications of CLR for, 6–7

JVM (Java Virtual Machine)

versus CLR, 9

## K

keys

adding with Table Designer, 317–319

in databases, definition of, 42

role in databases, 42

keyset cursors, explanation of, 265

## L

labels, binding to existing message queues with, 461

**LastName** column in tblUser column for CUser class, details of, 514

LDAP display names for users, Web site for, 425

LDAP (Lightweight Directory Access Protocol), introduction to, 413–414

LDAP query filters, Web sites for, 425

LDAP syntax, examining, 420–421

less than (<) column comparison symbol, role in Query Designer join types, 323

less than or equal to (<=) column comparison symbol, role in Query Designer join types, 323

line numbers, using in VS .NET IDE text editors, 24

link tables, using with many-to-many relationships, 41

linked servers

accessing Microsoft Exchange Server as, 442–447

creating, 443–444

creating views on, 447

dropping, 446

setting up, 442

**List** property of **CurrencyManager** class, description of, 540

**LoadDataRow DataTable** class method, description of, 222

local processing resources, performance resources optimization of, 369

**Locale** property

of **DataSet** class, 198

of **DataTable** class, 219

**LocalName XmlReader** class property, 162

locking types, explanations of, 265–276

LoginName column in tblUser column for CUser class, details of, 514,

518, 523

lookup keys, role in databases, 42

**LookupNamespace XmlReader** class method, 164

## M

machine names, creating message queues with, 454–455

Macros IDE, accessing, 22–23

mail messages, sending with SMTP, 437

mail, retrieving from Active Directory with OLE DB .NET data providers, 432

Make Table queries, using Query Designer for, 332

Managed Classes in SQLXML 2.0, introduction to, 611

managed code definition of, 6

role in .NET Framework, 7

manifest components of assemblies, list of, 10

manipulation of databases, understanding, 33

manual data hooking versus data-bound controls, 525–526

manual transactions

aborting, 106

ADO.NET connection layer support for, 99

committing, 107

summary of, 109–110

many forms, 506–507

- many-to-many relationships, explanation of, 41
- mapping schema for XPath queries, displaying, 629–630
- Max Pool Size **ConnectionString** property value, details of, 70–71
- Max Pool Size value names, role in pooling connections for **SqlConnection**, 92
- MaxLength DataColumn** class property, description of, 251
- MDAC (Microsoft Data Access Components)
  - 2.6, required on your system, 61
  - 2.7, distributed with VS .NET, 61
- MDI (multiple document interface) mode, explanation of, 16
- merge **DataSet**, explanation of, 210
- Merge DataSet** class method, description of, 200
- merge failures, handling with **DataSet** class, 202–203
- MergeFailed DataSet** class event, 200
- Message Exception** class property, description of, 347
- message formatters, setting up for message queues, 464–467
- message journaling, explanation of, 488–489
- Message** property
  - of **OdbcError** class, 121
  - of **OdbcException** class, 122
  - of **OleDbError** class, 117
  - of **OleDbException** class, 118
- message queues
  - aborting transactions for, 483
  - assigning labels to, 458
  - binding to existing types of, 459–461
  - binding with labels, 461
  - clearing messages from, 472–473
  - committing transactions for, 482–483
  - controlling storage size of, 479–480
  - creating programmatically, 454–456
  - creating with Server Explorer, 289–290
  - deleting with Server Explorer, 290
  - displaying or changing properties in, 456–459
  - enabling authentication on, 491
  - enabling journaling on, 487
  - ending transactions for, 482–483
  - locating, 475–477
  - making transactional, 480–485
  - peeking at messages in, 467
  - picking specific messages from, 468–469
  - prioritizing messages in, 473–475
  - rejecting nonencrypted messages in, 496–497
  - removing, 477–479
  - removing messages after specified time elapse, 493
  - retrieving all messages from, 470
  - retrieving IDs of, 458–459
  - retrieving messages from, 463–467
  - sending and retrieving messages from, 466–467
  - sending messages to, 461–463
  - setting up message formatters for, 464–467
  - starting transactions for, 481
  - usage of, 449, 451–453
  - using journal storage with, 486–490
  - using system-generated type of, 485–490
  - using system journals with, 486–487
  - using transactions with, 484–485
- message queuing
  - using access control with, 499–502
  - using auditing with, 502
  - using authentication with, 490–495
  - using encryption with, 495–499
- MessageQueue** class, examining, 450
- MessageQueueTransaction** class, using, 483–485
- messages
  - deleting messages from, 290
  - enabling journaling on, 487–488
  - rejecting nonauthenticated type of, 491
  - removing from message queues, 472–473
  - removing from message queues after specified time elapse, 493
  - retrieving from journal storage, 489
  - sending and retrieving asynchronously, 470–472
  - sending and retrieving from message queues, 466–467
- metadata, generating for COM types, 277–278
- Microsoft Access, advisory about, 367–368
- Microsoft Data Access Components. *See* MDAC.
- Microsoft Exchange Server
  - accessing, 436–447
  - accessing as linked server from SQL Server, 442–447
  - retrieving contacts for UserMan user from, 438–439
  - reviewing content of sample folder with, 440–441

- Microsoft OLE DB Exchange Server Provider (ExOLEDB), using, 438–439
  - Microsoft OLE DB Provider for Internet Publishing (MSDAIPP), using, 439–441
  - Microsoft Visual Studio .NET documentation, role in VS .NET IDE Help system, 22
  - Microsoft.Data.Odbc** namespace, description of, 58
  - Microsoft.Jet.OLEDB.4.0 provider, description of, 61
  - Min Pool Size **ConnectionString** property value, details of, 72–73
  - Min Pool Size value names, role in pooling connections for **SqlConnection**, 92
  - MinimumCapacity DataTable** class property, description of, 220
  - MissingMappingAction** DataAdapter class property, description of, 172
  - MissingSchemaAction** DataAdapter class property, description of, 172
  - monikers, role in LDAP syntax, 420–421
  - Move\* XmlReader** class methods, 165–166
  - MoveTo DirectoryEntry** class method, description of, 419
  - MoveToAttribute XmlReader** class method, 165
  - MoveToContent XmlReader** class method, 165
  - MoveToElement XmlReader** class method, 165
  - MoveToFirstAttribute XmlReader** class method, 165
  - MoveToNextAttribute XmlReader** class method, 166
  - MSDAIPP (Microsoft OLE DB Provider for Internet Publishing), using, 439–441
  - MSDAORA provider, description of, 61
  - MSIL (Microsoft intermediate language), compilation of code to, 8
  - MSMQ (Microsoft Message Queue Server), explanation of, 449–450
  - multivalued dependencies, role in 4NF, 49
  - MySQL, advisory about, 368
- ## N
- n-tier applications, relationship to ADO.NET, 56
  - Name** property
    - of **DirectoryEntry** class, 418
    - of **SqlParameter** class, 612
    - of **XmlReader** class, 162
  - named parameters, executing SQL queries with, 623–625
  - named SQL transactions, beginning, 103
  - named transactions, tip about, 107
  - namespace pollution, definition of, 12
  - Namespace** property
    - of **DataColumn** class, 251
    - of **DataSet** class, 198
    - of **DataTable** class, 220
  - namespaces. *See also* data-related namespaces
    - determining for classes, 123
    - functionality of, 11–13
    - public status of, 13
  - NamespaceURI XmlReader** class property, 163
  - NameTable XmlReader** class property, 163
  - NativeError** property
    - of **OdbcError** class, 121
    - of **OleDbError** class, 117
  - NativeGuid** property of **DirectoryEntry** class, description of, 418
  - NativeObject** property of **DirectoryEntry** class, description of, 418
  - Nested DataRelation** class property, description of, 254
  - nested OleDb transactions, beginning, 105–106
  - nesting, definition of, 397
  - .NET Data Providers
    - Connection class in, 63–64
    - explanation of, 62–63
  - .NET-enabled applications, connecting to, 64
  - .NET Framework
    - components of, 4–9
    - cross-language inheritance in, 8–9
    - data-related namespaces in, 58
    - description of, 3–4
    - garbage collection in, 7–8
    - managed code in, 7
    - using COM components from within, 276–278

- .NET Framework class library, contents of, 13–14
- Net or Network Library
  - ConnectionString** property value, details of, 72–73
- Network Address **ConnectionString** property value, details of, 72–73
- network directory services, explanation of, 413
- network resources, performance
  - resources optimization of, 369
- New Project dialog box, displaying, 296
- New Value grid pane column in Query Designer, 326
- NewRow DataTable** class method, description of, 222
- NextResult** method of **DataReader** class, 159
- nodes, separating in Active Directory hierarchy, 420
- NodeType XmlReader** class property, 163
- non-row returning SQL statements, executing, 632
- non-row-returning string templates, executing, 632–633
- non-row-returning templates, executing, 633
- normal forms, explanation of, 46–51
- normalization in databases, explanation of, 46
- not equal to (<>) column comparison symbol, role in Query Designer join types, 323
- NotSupportedException** exception, handling for **DataReader**, 160
- null values
  - advisory when using
    - CommandBuilder** class, 190
  - checking in columns, 149–150
  - in databases, definition of, 36
  - role in databases, 36
- NullReferenceException** exception, explanation of, 350, 352
- O**
- O (organization) moniker, role in LDAP syntax, 421
- Object Browser, role in VS .NET IDE, 19–20
- object property values, manipulating with Active Directory, 426–429
- objects
  - binding to in Active Directory, 421–422
  - checking structural integrity with
    - DBCC, 371–372
  - determining for databases, 37
  - querying with **DObject** virtual name, 605–606
  - searching in Active Directory, 422–425
- objectSid retrieving from Active Directory with OLE DB .NET data providers, 432
- objUser object declaration, examining in Data Form Wizard, 536–537
- ODBC connection pooling, disabling, 94–96
- ODBC connection strings, setting up, 61–62
- ODBC object pooling, clearing, 96
- ODBC (Open Data Base Connectivity), Web site for, 96
- ODBC (Open Data Base Connectivity) data sources, accessing in ADO, 59
- ODBC standard escape sequences, Web sites for, 137
- OdbcCommand** class
  - instantiating, 126–127
  - properties of, 79, 135–137
  - usage of, 124
- OdbcConnection** class,
  - BeginTransaction** method of, 101
- OdbcConnection** data type, pooling connections of, 94–96
- OdbcConnection** exceptions, handling, 119–123
- OdbcConnection** managed connection, explanation of, 63–64
- OdbcDataAdapter** class, setting command properties in, 182–184
- OdbcDataReader** class, use of, 147
- OdbcError** class, examining, 119–120
- OdbcException** class, examining, 121–123
- ODBC .NET data provider, downloading, 58
- OdbcTransaction** classes, nesting transactions with, 106
- OLE DB connection pooling, disabling, 93
- OLE DB drivers
  - in ADO.NET connected layer, 59
  - specifying when connecting, 61–62
- OLE DB .NET data provider, accessing Active Directory with, 429–436

- OLE DB (Object Linking and Embedding Data Base) specification, explanation of, 59
  - OLE DB object pooling, clearing, 93–94
  - OLE DB providers
    - compatibility with OLE DB.NET providers, 61
    - selecting for data sources with Server Explorer, 283
    - specifying for Active Directory connections, 430–431
    - specifying when connecting, 61–62
  - OLE DB.NET providers compatible with OLE DB providers, list of, 61
  - OleDbCommand** class
    - properties of, 132–134
    - usage of, 124
  - OleDbCommand** object, instantiating, 124–126
  - OleDbConnection** class
    - methods of, 81–84
    - properties of, 78
  - OleDbConnection** data type, pooling connections of, 93–94
  - OleDbConnection** exceptions, throwing, 115–119
  - OleDbConnection** managed connection, explanation of, 63–64
  - OleDbDataAdapter** class, setting command properties in, 181–182
  - OleDbDataReader** class, use of, 147
  - OleDbError** class, examining, 116–117
  - OleDbException** class
    - examining, 117–119
    - methods of, 119
    - traversing, 116
  - OleDbTransaction** class, nesting transactions with, 105–106
  - one-to-many relationships, explanation of, 40
  - one-to-one relationships, explanation of, 39–40
  - OOP (Object Oriented Programming)
    - C# keywords related to, 510–511
    - overriding properties in derived classes with, 512–513
    - overview of, 506–513
    - resources for, 506
    - role of encapsulation in, 510
    - role of implementation inheritance in, 509–510
    - role of inheritance in, 507–510
    - role of polymorphism in, 506–507
  - open connection, explanation of, 85–86
  - Open** member of **ConnectionState** Enum, description of, 89
  - Open** method
    - of **OdbcConnection** class, 83
    - of **OleDbConnection** class, 82
    - of **SqlConnection** class, 81
    - throwing exceptions, 115
  - optimistic locking, explanation of, 265, 268–276
  - optimization issues, explanation of, 368–373
  - Option setting for message queue encryption, explanation of, 498
  - Options dialog box, accessing, 24–25
  - Options dialog box in SQL Editor, displaying, 334
  - Or . . . grid pane column in Query Designer, 326
  - Oracle, advisory about, 368
  - Oracle Database Project, downloading, 392
  - Oracle stored functions, running, 391–392
  - Oracle stored procedures
    - retrieving result set from, 396
    - running, 392–397
  - order systems, typical objects for, 38
  - Ordinal DataColumn** class property, description of, 251
  - organization of databases, understanding, 32
  - orphaned child tables, preventing with referential integrity, 45
  - OU (organizational unit) moniker, role in LDAP syntax, 420–421
  - Output grid pane column in Query Designer, 326
  - override** keyword in C#, relationship to OOP, 511
  - ownership chain, definition of, 391
- ## P
- Packet Size **ConnectionString** property value, details of, 72–73
  - PacketSize SqlConnection** class property, details of, 77
  - Page\_Load** event procedure, displaying, 556–557
  - Parameters** property
    - of **OdbcCommand** class, 136
    - of **OleDbCommand** class, 133
    - of **SqlCommand** class, 130
  - parent classes, specifying in CUser class, 578
  - Parent** property of **DirectoryEntry** class, description of, 418
  - parent tables, explanation of, 39

- ParentColumns DataRelation** class
  - property, description of, 254
- ParentKeyConstraint DataRelation**
  - class property, description of, 254
- ParentRelations DataTable** class property, description of, 220
- ParentTable DataRelation** class property, description of, 254
- Password column in **tblUser** column for **CUser** class, details of, 514
- Password or Pwd **ConnectionString** property value, details of, 72–73
- Password** property of **DirectoryEntry** class, description of, 418
- Path** property of **DirectoryEntry** class, description of, 418
- PE (portable executable) files, storage of compiled code in, 8
- Peek** and **Receive** methods of **MessageQueue** class, explanation of, 464
- Pending** member of **MessageQueueTransactionStatus** Enum, description of, 483
- perfmon (Performance Monitor), functionality of, 372
- performance degradation, troubleshooting, 371–373
- performance resources optimization table, 369
- Permissions manifest component, description of, 10
- Persist Security Info **ConnectionString** property value, details of, 72–73, 76
- pessimistic locking, explanation of, 266–268
- polymorphism, role in OOP, 506–507
- pooling connections
  - in ADO.NET connected layer, 90–96
  - of data type **OdbcConnection**, 94–96
  - of data type **OleDbConnection**, 93–94
  - of data type **SqlConnection**, 92–93
- Pooling **ConnectionString** property value, details of, 74–75
- pools
  - removing connections from, 92
  - testing for, 92
- populate **DataSet** with **DataAdapter** class, 203–206
- populate **DataTable**, explanation of, 227
- Position** property of **CurrencyManager** class, description of, 540
- positional parameters, executing SQL queries with, 625–627
- Prefix** property
  - of **DataColumn** class, 251
  - of **DataSet** class, 198
  - of **DataTable** class, 220
  - of **XmlReader** class, 163
- Prepare** Command class method, description of, 139
- PRI (procedural referential integrity) in databases, explanation of, 45
- primary keys
  - in databases, definition of, 42
  - role in databases, 42–43
  - setting with Table Designer, 316–317
- PrimaryKey DataTable** class property, description of, 220
- privacy for message queue encryption, explanation of, 497
- private message queues
  - creating on local machines, 454–456
  - versus public message queues, 453–454
  - retrieving, 475–476
  - using with Server Explorer, 288
- private variables, creating for **CUser** class, 515–516
- procedures, using multiple exception handlers in, 345–346
- processing resources, determining for optimization, 370
- programming concepts, review of, 4–14
- properties
  - adding to Active Directory, 427–429
  - checking existence with Active Directory, 426
  - displaying and changing for message queues, 456–459
  - editing with Active Directory, 427
  - overriding in derived classes with OOP, 512–513
  - using local cache for, 426
- Properties** property of **DirectoryEntry** class, description of, 418
- Property Pages dialog box in Table Designer, displaying, 318–319
- PropertyCollection** class in **System.DirectoryServices** namespace, description of, 416
- PropertyValueCollection** class in **System.DirectoryServices** namespace, description of, 416
- Provider **ConnectionString** property value, details of, 74–75

- provider messages, handling in ADO.NET connection layer, 97–98
  - Provider OleDbConnection** class property, details of, 78
  - providers. *See* OLE DB providers
  - public message queues
    - creating, 455
    - versus private message queues, 453–454
    - retrieving, 476–477
    - using with Server Explorer, 288
  - public properties, hooking up to data sets in UserMan example application, 576–578
  - public status of namespaces, advisory about, 13
  - PWD **ConnectionString** property value, details of, 72–73
- Q**
- queries
    - executing from browsers using file-based templates, 606–610
    - executing with Query Designer, 330
  - Query Analyzer, functionality of, 372
  - Query Builder, accessing, 335
  - Query Designer
    - changing join types with, 323–324
    - creating select query with, 321
    - creating SQL statements with, 325
    - diagram pane in, 322–325
    - executing queries with, 330
    - grid pane in, 325–327
    - grouping and sorting output in, 324–325
    - hiding and showing panes in, 328–329
    - removing tables with, 323
    - Results pane in, 328
    - sorting columns with, 324
    - SQL pane in, 327–328
    - using DELETE queries with, 331–332
    - using INSERT queries with, 333
    - using Make Table queries with, 332
    - using SELECT queries with, 331
    - using UPDATE queries with, 331
    - using Verify SQL Syntax facility in, 329–330
  - Query Editor, producing SQL statements with, 335–336
  - query types, examining in Query Designer, 330–334
  - QuoteChar XmlReader** class property, 163
- R**
- RAW SELECT . . . FOR XML statement keyword, description of, 588
  - RCWs (Runtime Callable Wrappers), using with COM types, 277
  - RDBMSes (relational database management systems), planning move to, 375
  - RDN (relative distinguished name), role in Active Directory, 420
  - Read** method of **DataReader** class, 159
  - Read** method of **XmlReader** class, 166
  - read-only data, retrieving from views in code, 401–402
  - read-only mode, generating data-bound Web forms in, 554
  - Read\* XmlReader** class methods, 166–167
  - ReadAttributeValue** method of **XmlReader** class, 166
  - ReadCommitted** member of **IsolationLevel** Enum, description of, 102
  - ReadElementString** method of **XmlReader** class, 166
  - ReadEndElement** method of **XmlReader** class, 166
  - ReadInnerXml** method of **XmlReader** class, 166
  - ReadOnly DataColumn** class property, description of, 251
  - ReadOuterXml** method of **XmlReader** class, 167
  - ReadStartElement** method of **XmlReader** class, 167
  - ReadState XmlReader** class property, 163
  - ReadString** method of **XmlReader** class, 167
  - ReadUncommitted** member of **IsolationLevel** Enum, description of, 102
  - ReadXml DataSet** class method, description of, 200
  - ReadXmlSchema DataSet** class method, description of, 201
  - Receive** and **Peek** methods of **MessageQueue** class, explanation of, 464
  - records, role in databases, 36
  - RecordsAffected** property of **DataReader** class, description of, 151
  - Recordset** class versus **DataSet** class, 194–196
  - reference points, saving in transactions, 104–105
  - Referenced Assemblies manifest component, description of, 10
  - ReferenceEquals** method, comparing with, 88

- referential integrity in databases, explanation of, 44–45
- Refresh CurrencyManager** class
  - method, description of, 541
- RefreshCache DirectoryEntry** class
  - method, description of, 419
- Register SQL Server Instance dialog box, displaying, 291
- Registry, explaining absence of, 4
- RejectChanges** method
  - of **DataRow** class, 248
  - of **DataSet** class, 201
  - of **DataTable** class, 223
  - using with **DataSet** objects, 216–218
- relational database design, explanation of, 37–38
- Relational Database Model, explanation of, 36
- relational databases, key aspects of, 35–51
- relational versus hierarchical databases, 33–35
- RelationName DataRelation** class property, description of, 254
- Relations DataSet** class property, description of, 199
- relationship names, showing in database diagrams, 312
- relationships
  - adding with Database Designer, 311
  - creating with Table Designer, 320
  - deleting with Database Designer, 311
  - explanation of, 39
- ReleaseObjectPool** method
  - clearing ODBC object pooling with, 96
  - clearing OLE DB object pooling with, 93–94
  - of **OdbcConnection** class, 84
  - of **OleDbConnection** class, 82
- RemoveAt CurrencyManager** class
  - method, description of, 541
- Rename DirectoryEntry** class method, description of, 420
- RepeatableRead** member of **IsolationLevel** Enum, description of, 102
- Reset** method
  - of **DataSet** class, 201
  - of **DataTable** class, 223
- ResetCommandTimeout** Command
  - class method, description of, 139
- ResolveEntity** method of **XmlReader** class, 167
- result sets
  - appending to streams, 621–622
  - representation in ADO.NET, 261
  - retrieving from Oracle stored procedures, 396
  - retrieving in **XmlReader** class, 620
  - saving to streams, 620–621
- ResultPropertyCollection** class in **System.DirectoryServices** namespace, description of, 416
- ResultPropertyValueCollection** class in **System.DirectoryServices** namespace, description of, 416
- Results pane of Query Designer, functionality of, 328
- ResumeBinding CurrencyManager** class method, description of, 541
- return values and arguments, running stored procedures with, 385–387
- RETURN\_VALUE, retrieving from stored procedures, 390–391
- Rollback** method
  - role in aborting manual transactions, 106
  - of Transaction class, 109
- row and column change events, examining order of, 232–233
- row changes, handling in **DataTable** objects, 235–236
- row deletions, handling in **DataTable** objects, 236–238
- row updates, handling in ADO.NET connection layer, 185–188
- RowChanged DataTable** class event, description of, 224
- RowChanging DataTable** class event, description of, 224
- RowDeleted DataTable** class event, description of, 224
- RowDeleting DataTable** class event, description of, 224
- RowError DataRow** class property, description of, 245
- RowFilter DataView** class property, description of, 239
- rows
  - appending to tables with INSERT Results queries, 333
  - copying in **DataTable** objects, 230–232
  - reading in **XmlReader** class, 168–169
  - retrieving from stored procedures, 382
  - retrieving from stored procedures with input arguments, 384–385

- rows (*continued*)
    - retrieving in views, 402
    - role in databases, 36
    - in database tables, definition of, 36
  - Rows DataTable** class property,
    - description of, 220
  - rows of data sources
    - navigating in bound controls, 543
    - retrieving for data-bound controls, 542
  - RowState DataRow** class property,
    - description of, 245
  - RowStateFilter DataView** class property,
    - description of, 239
  - RowUpdated** DataAdapter class event,
    - description of, 175
  - RowUpdating** DataAdapter class event,
    - description of, 175
  - Run On dialog box, displaying, 302
  - running transactions, determining
    - isolation levels of, 107–108
- S
- sa (system administrator), role in SQL Servers, 293
  - samAccountName retrieving from
    - Active Directory with OLE DB .NET data providers, 432
  - Save** method of Transaction class,
    - description of, 109
  - save points, using with **SqlTransaction** class, 104–105
  - scalar values, returning with stored procedures, 389–391
  - SchemaClassName** property of **DirectoryEntry** class,
    - description of, 418
  - SchemaEntry** property of **DirectoryEntry** class,
    - description of, 418
  - SchemaNameCollection** class in System.DirectoryServices namespace, description of, 416
  - SchemaPath** property, role in executing XPath queries, 630
  - script editing with SQL Editor, performing, 334–337
  - script templates, editing and using with SQL Editor, 336
  - scripts
    - placing in command files, 303–304
    - running in IDEs, 302
    - saving with SQL Editor, 336
  - sealed** keyword in C#, relationship to OOP, 511
  - search Active Directory, explanation of, 422–424
  - search **DataTable**, explanation of, 229–230
  - search **DataView**, explanation of, 243
  - SearchResult** class in **System.DirectoryServices** namespace, description of, 416
  - SearchResultCollection** class in **System.DirectoryServices** namespace, description of, 416
  - security, using views for, 398
  - Select DataTable** class method,
    - description of, 223
  - SELECT . . . FOR XML AUTO, ELEMENTS output, 589–590
  - Select** method, finding rows in **DataTable** objects with, 229–230
  - SELECT queries, using Query Designer for, 331
  - SelectCommand** DataAdapter class property, description of, 172
  - SelectCommand** property, setting, 178, 189
  - SELECT . . . FOR XML AUTO, XMLDATA output, 590–591
  - SELECT . . . FOR XML RAW output, 590
  - SELECT . . . FOR XML statement keywords, list of, 588–589
  - Serializable** member of **IsolationLevel** Enum, description of, 102
  - Server **ConnectionString** property value, details of, 74–75
  - SERVER **ConnectionString** property value, details of, 74–75
  - Server Explorer
    - adding servers with, 286–287
    - Connect As dialog box options in, 287
    - connecting servers as different users with, 286–287
    - creating database objects with, 285
    - creating SQL Server databases with, 292–295
    - creating triggers with, 407–412
    - deleting and dropping SQL Server databases with, 295
    - deleting data connections with, 285
    - deleting servers with, 295–296
    - explanation of, 25–26
    - handling data connections with, 282–285
    - introduction to, 281–282

- registering SQL Server instances with, 291
  - selecting message queues in, 478
  - unregistering SQL Server instances with, 292
  - using message queues with, 288–290
  - using server resources with, 288–295
  - using with SQL Server databases, 290–295
- server processing resources, performance resources
  - optimization of, 369
- server resources, using with Server Explorer, 288–295
- server-side cursors, explanation of, 262–263
- server-side processing, definition of, 367
- servers
  - adding with Server Explorer, 286–287
  - connecting as different users with Server Explorer, 286–287
  - deleting with Server Explorer, 295–296
- ServerVersion** property
  - of **OdbcConnection** class, 79
  - of **OleDbConnection** class, 78
  - of **SqlConnection** class, 77
- SET ANSI\_DEFAULTS T-SQL statement, role in RDBMS migration from SQL Server, 375
- set**, property arguments, checking length of, in **CUser** class, 517
- SetColumnError DataRow** class property, description of, 248
- SetParentRow DataRow** class property, description of, 248
- SetPermissions** method, using with access control for message queues, 501–502
- SimpleStoredProcedure**, displaying output from, 380
- Skip XmlReader** class method, 167
- SMTP (Simple Mail Transfer Protocol), sending mail messages with, 437
- SOAP (Simple Object Access Protocol), based on XML, 5
  - uses HTTP protocol, 5
  - XML Web services based on, 5
- Solution Explorer
  - finding database projects in, 298–299
  - locating Show All Files button in, 535
  - running SQL scripts with, 336–337
  - switching to Class View in, 507
  - sort **DataView**, explanation of, 244–245
  - Sort DataView** class property, description of, 239
  - Sort Order grid pane column in Query Designer, 326
  - Sort Type grid pane column in Query Designer, 326
  - SortOption** class in **System.DirectoryServices** namespace, description of, 416
  - Source** property
    - of **Exception** class, 347
    - of **OdbcError** class, 121
    - of **OdbcException** class, 122
    - of **OleDbError** class, 117
    - of **OleDbException** class, 118
  - sp\_addlinkedserver** system stored procedure, resource for, 442–443
  - sp\_dropserver** system stored procedures, resource for, 446
  - SQL Dialect, Web site for, 434
  - SQL Editor
    - editing and using script templates with, 336
    - running SQL scripts with, 336–337
    - saving scripts with, 336
    - using, 334–337
  - SQL pane of Query Designer, functionality of, 327–328
  - SQL queries
    - executing with named parameters, 623–625
    - executing with positional parameters, 625–627
    - executing with **SqlXmlCommand** class, 620–624
  - SQL Script database object template, description of, 301
  - SQL scripts, running with SQL Editor, 336–337
  - SQL Server 7.0, advisory about, 367
  - SQL Server databases. *See also* databases
    - accessing Microsoft Server as linked server from, 442–447
    - creating nondefault values and properties for, 294
    - creating simple stored procedures with, 376
    - creating with Server Explorer, 292–295
    - deleting and dropping with Server Explorer, 295
    - functionality of stored procedures in, 392
    - resources for, 371

- SQL Server databases (*continued*)
  - retrieving from, with **SqlXmlAdapter** class, 614–619
  - updating with **SqlXmlAdapter** class, 618–619
  - using Server Explorer with, 290–295, 290–295
  - using stored procedures with, 375–379
- SQL Server Enterprise Manager, viewing stored procedure dependencies with, 391
- SQL Server instances
  - registering with Server Explorer, 291
  - unregistering with Server Explorer, 292
- SQL Server .NET Data Provider versus SQLXML 2.0 Managed classes, 611
- SQL standards, Web site for, 327
- SQL statements
  - creating in SQL pane of Query Designer, 325
  - executing non-row-returning type of, 632
  - producing with Query Editor, 335–336
- SQL syntax, verifying with Query Designer, 329–330
- SqlCommand** class
  - properties of, 130–131
  - usage of, 124
- SqlCommand** object, instantiating, 128–129
- SqlCommandBuilder** class, using, 190
- SqlConnection** class, **BeginTransaction** method for, 100–101
- SqlConnection** class exceptions
  - catching, 357
  - handling, 110–115
  - methods of, 80–81
  - properties of, 77
- SqlConnection** data type, pooling connections for, 92–93
- SqlConnection** managed connection, explanation of, 63–64
- SqlDataAdapter** class
  - instantiating, 176–178
  - setting command properties of, 179–180
- SqlDataReader** class and object, instantiating, 147–148
- SqlInfoMessageEventArgs** class
  - argument, 97–98
  - Message** property, 98
  - Source** property, 98
- SQLOLEDB provider, description of, 61
- SQLState** property
  - of **OdbcError** class, 121
  - of **OleDbError** class, 117
- SqlTransaction** class
  - nesting transactions with, 104–105
  - using transaction save points with, 104–105
- SQLXML 2.0
  - advisory about direct URL queries in, 606
  - advisory about using template string method with, 617
  - configuring ISAPI extension for, 593–598
  - executing directory queries from browser in, 601–606
  - executing file-based XML templates from code in, 617
  - executing queries from browsers with file-based templates, 606–610
  - installing, 592–593
  - introduction to, 591
  - introduction to Managed Classes in, 611
  - querying tables in, 601–603
  - sample connection string in, 614
  - sample template query with parameters in, 608–609
- SQLXML 2.0 Managed Classes, using DiffGrams and UpdateGrams with, 619
- SqlXmlAdapter** class
  - examining, 612–619
  - retrieving SQL Server data with, 614–619
  - updating SQL Server data with, 618–619
- SqlXmlAdapter** objects, instantiating, 613–614
- SqlXmlCommand** class
  - executing SQL queries with, 620–623
  - introduction to, 619
  - populating **DataSets** with, 615–616
  - updating data sources with, 631–635
- SqlXmlCommand** objects, instantiating, 619
- SqlXmlParameter** class, examining, 612
- StackTrace** property
  - of **Exception** class, 347
  - of **OdbcException** class, 122
  - of **OleDbException** class, 118
- stand-alone applications versus distributed applications, 368
- standard HTML programming model for ASP.NET, explanation of, 5

- State**, comparing to **ConnectionState**, 89
  - State** property
    - of **OdbcConnection** class, 79
    - of **OleDbConnection** class, 78
    - of **SqlConnection** class, 77
  - StateChange** **Connection** class event, details of, 85
  - static cursors, explanation of, 264
  - storage capability of databases, understanding, 32
  - Stored Procedure Script database object template, description of, 301
  - stored procedures, 372–373
    - creating, 375–379
      - creating with arguments, 382–384
      - creating with arguments and return values, 385–387
    - introduction to, 373
    - reasons for use of, 374–375
    - renaming, 391
    - retrieving rows and output values from, 388–389
    - retrieving rows from, 382
    - running from code, 380–382
    - running from IDE, 379–380
    - running with arguments from IDE, 384
    - running with Oracle, 392–397
    - syntax testing of, 387
    - using RETURN statement with, 389–391
    - using with arguments, 384–385
    - viewing dependencies for, 391
  - streams
    - appending result sets to, 621–622
    - saving result sets to, 620–621
  - strong typing versus weak typing, example of, 196
  - SuspendBinding CurrencyManager** class
    - method, description of, 541
  - syntax for creating namespaces, 12
  - system-generated message queues, examining, 485–490
  - system journals, using with message queues, 486–487
  - system message queues, using with Server Explorer, 288
  - System** .NET root namespace, explanation of, 11–12
  - System Stored Procedures. *See* stored procedures, 372–373
  - System\*** data-related namespaces, list of, 58
  - System.Data** namespace, description of, 58
  - System.Data.OleDb** namespace, description of, 58
  - System.Data.SqlClient** namespace, description of, 58
  - System.DirectoryServices** namespace, examining in Active Directory, 415–417
  - SystemException** exception type, 350
- T**
- \*.tlb (type libraries), role in generating metadata for COM types, 277
  - T-SQL, adding linked Microsoft Exchange Server with, 442–443
  - tabbed documents mode, explanation of, 16
  - Table Designer
    - adding columns to tables with, 315–316
    - adding constraints with, 319–320
    - adding indexes and keys with, 317–319
    - creating relationships with, 320
    - creating tables with, 314–315
    - setting primary keys with, 316–317
    - using triggers with, 320
  - Table grid pane column in Query Designer, 326
  - Table** property
    - of **DataColumn** class, 251
    - of **DataRow** class property, description of, 245
    - of **DataView** class, 239
  - Table Script database object template, description of, 301
  - table views, changing for database diagrams, 313
  - TableMappings** **DataAdapter** class property, description of, 172
  - TableName DataTable** class property, description of, 220
  - tables
    - adding and showing in tables with Query Designer, 322
    - adding with Database Designer, 309
    - creating with Database Designer, 309–313
    - creating with Table Designer, 314–315
    - deleting and removing with Database Designer, 309
    - in databases, definition of, 36
    - querying with SQLXML 2.0, 601–603
    - removing with diagram pane of Query Designer, 323
    - role in databases, 36
    - sizing automatically in database diagrams, 313

- tables and columns, choosing in Data Form Wizard, 532
- tables and views, choosing in Data Form Wizard, 531
- Tables DataSet** class property, description of, 199

- TargetSite** property of **OdbcException** class, details of, 122
- TargetSite** property of **OleDbException** class, details of, 118
- Task List in VS .NET IDE, explanation of, 27–28
- tblLog table in UserMan database schema, explanation of, 52
- tblRights table in UserMan database schema, explanation of, 52
- tblUser columns for CUser class, list of, 514
- tblUser table in UserMan database schema, explanation of, 52
- tblUser\_Update trigger, displaying, 409
- tblUserRights table in UserMan database schema, explanation of, 52
- TCP/IP (Transmission Control Protocol/Internet Protocol), role in connectionless and connection oriented programming, 450
- TDS (tabular data stream) protocol, role in .NET Data Provider for SQL Server, 59
- template string method, advisory in SQLXML 2.0, 617
- templates
  - advisory about, 606
  - executing as string templates, 632–633
  - specifying with SQLXML 2.0, 602–603
- text editors
  - using in VS .NET IDE, 24
  - using SQL Editor, 334–337
- throw** statements, using, 356–357
- Toolbox in VS .NET IDE, explanation of, 27
- tools, modifying in VS .NET IDE, 24–25
- ToString** method
  - of **OdbcException** class, 123
  - of **OdbcConnection** class, 84
  - of **OleDbConnection** class, 82
  - of **OleDbException** class, 119
  - of **SqlConnection** class, 81
- transaction boundaries, defining in ADO.NET connected layer, 99
- Transaction class
  - methods of, 109
  - properties of, 108
- Transaction** property
  - of **OdbcCommand** class, 136
  - of **OleDbCommand** class, 133
  - of **SqlCommand** class, 131
- transaction save points, using with **SqlTransaction** class, 104–105
- transactional message queues, creating, 481
- transactional private message queues, creating, 456
- transactions
  - aborting for message queues, 483
  - beginning with nondefault isolation levels, 102
  - committing for message queues, 482–483
  - ending for message queues, 482–483
  - functionality of, 98
  - locking data at data sources with, 266–268
  - nesting with **OdbcTransaction** class, 106
  - nesting with **OleDbTransaction** class, 105–106
  - nesting with **SqlTransaction** class, 104–105
  - saving reference points in, 104–105
  - starting for message queues, 481
  - using with message queues, 484–485
- trigger and catch concurrency violation, example of, 269–270
- Trigger Script database object template, description of, 301
- triggers
  - advisory about, 406
  - creating, 407–412
  - introduction to, 403–404
  - invoking and catching exception raised example, 410–411
  - locating after saving, 409
  - reasons for use of, 406
  - using with Table Designer, 320
  - viewing source for, 412
- Trusted\_Connection **ConnectionString** property value, details of, 74–75
- try** blocks, role in filtering exceptions, 355
- try** statements, role in exception handling, 344
- Type Reference manifest component, description of, 10

typed data sets  
 in ADO.NET disconnected layer, 196  
 creating with DataSet Designer,  
 338–340  
 creating with XML Designer, 338

## U

UID **ConnectionString** property value,  
 details of, 74–75

**Unique DataColumn** class property,  
 description of, 251

unmanaged code, definition of, 6

**Unspecified** member of **IsolationLevel**  
 Enum, description of, 102

untyped data sets in ADO.NET discon-  
 nected layer, explanation of,  
 196

update data source using DataAdapter  
 class, 206–209

**Update** DataAdapter class method,  
 description of, 174

UPDATE queries, using Query Designer  
 for, 331

**UpdateCommand** DataAdapter class  
 property, description of, 172

**UpdatedRowSource** property  
 of **OdbcCommand** class, 137  
 of **OleDbCommand** class, 134  
 of **SqlCommand** class, 131  
 throws **ArgumentException**  
 exception, 145–146

UpdateGrams, advisory about using  
 with SQLXML 2.0 Managed  
 classes, 619

URLs (uniform resource locators), advi-  
 sory about querying with, 606

**UsePropertyCache** property of  
**DirectoryEntry** class,  
 description of, 418

User ID **ConnectionString** property  
 value, details of, 74–75

user permissions, setting programmati-  
 cally, 501

user properties  
 adding to Active Directory, 428  
 editing with Active Directory, 427  
 manipulating with Active Directory,  
 428–429

UserMan Properties dialog box, display-  
 ing, 433–434

UserMan database schema, 51–52

UserMan example application  
 adding Active Directory objects to,  
 579–581  
 adding command object parameters  
 to, 575–576

building as **DataSet** object, 256–261  
 calling Active Directory class in, 581  
 conformity to 5NF, 53  
 creating additional objects for,  
 581–582

creating select query in, 321

creating stored procedures for  
 accessing database tables in,  
 584

creating triggers with, 407–412

creating views in, 399–400

creating Web client for, 583

creating Windows client for, 582

downloading classes for, 567

exception handling in, 586

exposing functionality with Web ser-  
 vices, 585–586

filling data sets in, 576

hooking up public properties to data  
 sets in, 576–578

identifying information and objects  
 in, 565–566

instantiating and initializing data  
 adapters in, 574–575

instantiating command objects in,  
 573–574

instantiating **DataSet** objects in, 574

introduction to, 51–53

logging to event log in, 583–584

opening and closing connection to,  
 570–573

optimizing, 583–586

passing connection object to various  
 classes in, 584

retrieving contacts from Exchange  
 Server 2000, 438–439

schema for, 51–52

securing Password column in user  
 table of, 583

setting up database security for,  
 584–585

setting up triggers for enforcing busi-  
 ness rules in, 584

specifying parent classes in, 578

using constants for table and column  
 names in, 585

using local transactions with, 585

Web site for, 57

**Username** property of **DirectoryEntry**  
 class, description of, 418

userPrincipalName retrieving from  
 Active Directory with  
 OLE DB .NET data providers,  
 432

users, retrieving SID with Active  
 Directory, 435–436

**using** statement  
 importing namespaces into classes  
 with, 58  
 uspGetRETURN\_VALUE stored procedure, displaying, 390  
 uspGetUsers stored procedures, displaying, 381  
 uspGetUsersAndRights stored procedure, displaying, 386–388  
 uspGetUsersByLastName stored procedure, displaying, 383
